epilepsy may limit
opportunity...

Dilantin®
(diphenylhydantoin)

PARKE-DAVIS

extends horizons

This agent "...has brought new hope to an entire generation of seizure patients....With judicious use, it may be said that it alone is responsible for the prevention of more seizures than any other drug."*

DILANTIN (diphenylhydantoin) can help your epileptic patient to earn a livelihood...to prove his worth...and to share in the daily give-and-take as a full-fledged member of the workaday world.

Indications: Grand mal epilepsy and certain other convulsive states.

Precautions: Toxic effects are infrequent: allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Eruptions then usually subside. Though mild and rarely an indication for stopping dosage, gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered, especially in children, adolescents, and young adults. During initial treatment, minor side effects may include gastric distress, nausea, weight loss, transient nervousness, sleeplessness, and a feeling of unsteadiness. All usually subside with continued use. Megaloblastic anemia, aplastic anemia, leukopenia, granulocytopenia and pancytopenia have been reported. Nystagmus may develop. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. Periodic examination of the blood is advisable.

DILANTIN (diphenylhydantoin sodium) is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm.

BSP® DISPOSABLE UNIT

H.W.&D. BRAND OF SULFOBROMOPHTHALEIN SODIUM INJECTION, U.S.P.

(50 mg. per ml.)

Bromsulphalein (BSP), one of the most sensitive diagnostic agents for evaluating liver function, is now available in a new Disposable Unit. Each "unit" contains: A sterile BSP syringe calibrated in milliliters and pounds (utilizing the 5 mg./kg. BSP dosage schedule), a sterile disposable needle, alcohol swab and a 7.5 or 10 ml. size ampule of BSP.

The precalibrated dosage schedule imprinted on the syringe barrel makes weight calculations unnecessary—saving time and assuring proper administration of the dye, regardless of patient-weight.

Literature on indications and dosage available on request.

The NEW BSP DISPOSABLE UNIT is supplied in 7.5 and 10 ml. sizes in boxes of 10's and 25's.

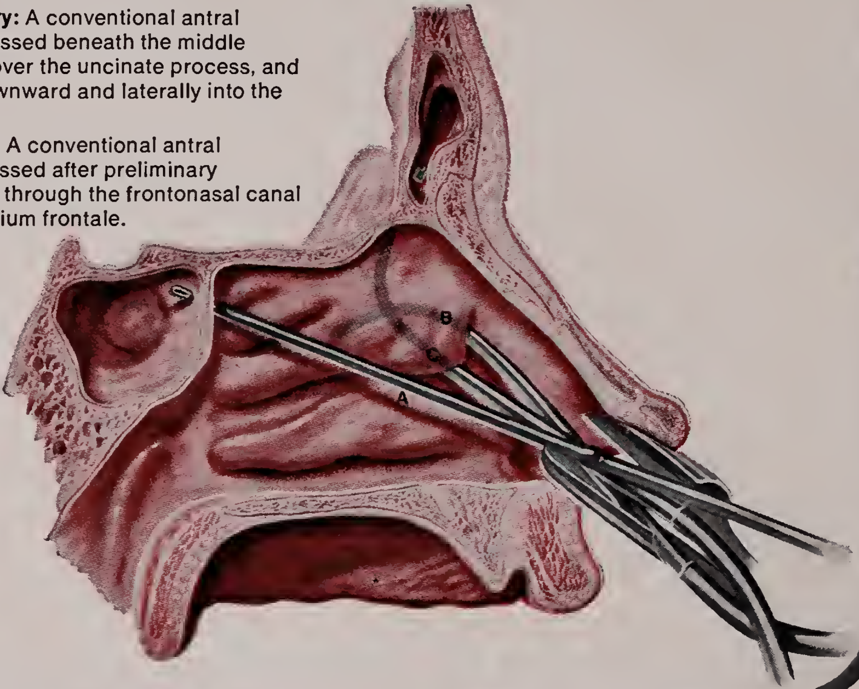
A rhinologic approach to the sinuses
Sagittal anatomical section of nasal cavity showing approach for probing or irrigation by cannulas.

A—Sphenoid: A sphenoid cannula (under 13.5 cm.) passed around the middle and superior turbinates to the anterior wall of the sinus through its ostium.

B—Maxillary: A conventional antral cannula passed beneath the middle turbinate, over the uncinate process, and rotated downward and laterally into the ostium.

C—Frontal: A conventional antral cannula passed after preliminary maneuvers through the frontonasal canal into the ostium frontale.



In colds and sinusitis

Neo-Synephrine® sooner

hydrochloride
(Brand of phenylephrine hydrochloride)

can help prevent emergency measures later

Before complications arise in colds and sinusitis, Neo-Synephrine solutions and sprays reduce nasal turgescence on contact — to promote essential aeration and drainage. Turbinates shrink, sinus ostia open and drainage is freed. Relief is instant and the threat of complications is lessened.

In the treatment of sinusitis, the 1/4 per cent solution is a preferred vasoconstrictor, "...most closely approximating physiologic composition with the least 'rebound' tendency...."* Gentle Neo-Synephrine is well tolerated by delicate respiratory tissues. Systemic effects are practically nil, post-therapeutic turgescence is minimal and repeated applications do not lessen its effectiveness. Neo-Synephrine has been a standard among vasoconstrictors since 1935.

Available in plastic nasal sprays for adults (1/2%) and children (1/4%), in solutions of 1/8, 1/4 or 1 per cent.

GENERAL INFORMATION

Authors

Manuscripts for consideration in Minnesota Medicine should be addressed to Office of Publication, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Papers should be typed double spaced on white paper with a wide margin. The first page should list the title, the name of the author (or authors), degree, and any institutional or other credits. Pages should be numbered consecutively. Tables should be typed and numbered and should have a brief descriptive caption.

Bibliographical references should be limited to twelve and should be typed in conformity to the method used by the Index Medicus. They should be numbered consecutively in the order in which they first appear in the text. Book references should give the name of the author, title, edition number, publisher, and the year.

Illustrations (photographs, tables, and graphs) should be submitted on separate sheets of paper and not combined in the text. Instructions for combining photographs are acceptable.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

"Gesundheit!"

...is just for the sneeze

but for symptomatic relief of the common cold...

'EMPRAZIL'®

TABLETS

Each layered tablet contains:

'Sudafed'® brand Pseudoephedrine Hydrochloride	20 mg.
'Perazil'® brand Chlorcyclizine Hydrochloride	15 mg.
Phenacetin	150 mg.
Aspirin	200 mg.
Caffeine	30 mg.

To relieve the aches, pains, fever and respiratory congestion of the common cold, flu or grippe with one product ...specify 'Emprazil'.

Caution: While pseudoephedrine is virtually without pressor effect in normotensive patients, it should be used with caution in hypertension. Also, while chlorcyclizine has a low incidence of antihistaminic drowsiness, the usual precautions should be observed.

Supplied: Bottles of 100 and 1000.

Also available with codeine—on prescription only—as **'EMPRAZIL-C'®** tablets

Complete literature available on request from Professional Services Dept. PML.

See the President's Letter on Page 61

because food is a factor

in oral penicillin therapy...

This is the breakfast used in the Griffith and Black study reported here.

consider V-CILLIN K®

POTASSIUM PHENOXYMETHYL PENICILLIN

Acid-stable V-Cillin K is much less affected by gastric acids than is oral penicillin G. In fact, comparative data show that V-Cillin K given with meals produces blood levels *twice* as high with just *half* the dose. Such pharmacologic characteristics provide your patients consistently dependable therapy. In addition, significant economy is achieved, since three to four times as much oral penicillin G is required to assure equivalent antibacterial activity.[1]

1. Griffith, R. S., and Black, H. R.: Current Ther. Res., *6*:253, 1964.

Indications: V-Cillin K is an antibiotic useful in the treatment of streptococcus, pneumococcus, and gonococcus infections and infections caused by sensitive strains of staphylococci.

Precautions: Although sensitivity reactions are much less common after oral than after parenteral administration, V-Cillin K should not be administered to patients with a history of allergy to penicillin. As with any antibiotic, observation for overgrowth of nonsusceptible organisms during treatment is important.

Usual Dosage Range: 125 mg. (200,000 units) three times a day to 250 mg. every four hours.

Supplied: Tablets V-Cillin K, 125 or 250 mg., and V-Cillin K, Pediatric, 125 mg. per 5-cc. teaspoonful, in 40, 80, and 150-cc.-size packages.

Additional information available to physicians upon request.

Pseudohypoparathyroidism

• Followup • Over • A • 26 • Year • Period

STEPHEN A. KIEFFER, M.D.*†
DONALD H. PETERSON, M.D.§
J. RICHARDS AURELIUS, M.D.*‡
St. Paul, Minnesota

PSEUDOHYPOPARATHYROIDISM was first described as a clinical syndrome by Albright and his group in 1942.[1] The sine qua non for its diagnosis is the presence of clinical and laboratory evidence of chronic parathyroid insufficiency without evidence of renal disease, steatorrhea, or generalized osteomalacia. As a corollary, prolonged daily injections of parathormone fail to produce the hypercalcemic response seen in individuals with idiopathic hypoparathyroidism.[2]

Surks and Levenson[3] have recently summarized the findings in 59 cases reported in the literature. All but three of these patients gave a history of convulsions or their tetanic equivalent. The typical habitus described by Albright** (short thick-set features with round facies) was found in 47 cases (79%). Twenty-nine cases (49%) showed ectopic calcifications in the subcutaneous tissues. Osseous dysplasia, chiefly involving the metacarpals and metatarsals, was noted in 31 patients (53%). Less frequent findings include calcification of the basal ganglia, lenticular opacities, mental retardation, and disturbed dentition.

Report of a Case

A 27-year-old Caucasian female was admitted to Ancker Hospital neuropsychiatric service in March, 1962, having recently been discharged from the care of the staff of the Mayo Clinic, who made the diagnosis of pseudohypoparathyroidism. She gave a history of lifelong obesity. At age 17 she left school, having reached only the ninth grade. For the previous three years, she had noted recurrent cramping and numbness in the extremities and an intolerance to cold.

Physical examination revealed a short (57 inches), fat (181 pounds) female, who answered questions haltingly. The face was round and the neck very short; the hands were chubby and the fingers short, with bilateral absence of the knuckle prominences for the fourth and fifth fingers. Trousseau's sign was positive, and Chvostek's sign was present. She had a normal female hair distribution.

Laboratory values included a serum calcium concentration of 6.9 mg. per cent (normal 9.0-11.0), serum phosphate of 5.2 mg. per cent (normal 3.0-4.5), and a 24-hour total urine calcium of 9.6 mg. (normal 50-300). Parathyroid hormone given intramuscularly in daily doses for two weeks failed to elicit a rise in the serum calcium. Her basic metabolic rate was minus 10 per cent, and a serum protein-bound iodine concentration was 3.8 micrograms per cent (normal 4.0-9.0). A 24-hour I^{131} uptake study showed a value of 12 per cent (normal 15-45). After TSH stimulation, however, this value rose to 37.5 per cent, establishing a diagnosis of secondary hypothyroidism. Radiographic findings will be described later. Her intelligence quotient (Wechsler full scale adult) was 63, placing her in the lowest one per cent of the adult population.

**See page 13.

A psychiatric consult was as follows: "Mixed psychoneurosis with depressive anxiety and hysterical features in a passive, obese woman of low mentality who is understandably quite concerned about her appearance."

The patient was treated with calcium lactate, calcium gluconate, and vitamin D_2. Although her mental state did not improve, the serum calcium and phosphate values rapidly attained the normal range. When last seen in this clinic in September, 1963, the serum calcium and phosphate were 9.5 and 3.5 mg. per cent respectively.

Radiographic Findings

Cusmano, Baker, and Finby[4] have summarized the radiographic findings in pseudohypoparathyroidism. The most frequent finding in their series was shortening of the fourth and fifth metacarpals and less frequently the first metacarpal. The fourth and fifth metatarsals also were often shortened. Less frequent radiographic findings have included calcification of the basal ganglia, ectopic calcifications in the soft tissues in the vicinity of the joints of the hands and feet, and thickening of the bony calvarium. The latter finding involves a widening of the diploic space rather than actual cortical thickening of the inner or outer tables of the skull. These authors also noted accelerated skeletal maturation in four of their six patients.

The Metacarpals and the Metatarsals

Films of our patient on the most recent admission are shown in Figures 1, 2, and 3. Figure 1 shows marked bilateral shortening of the fifth metacarpals and to a lesser degree of the fourth metacarpals. The shafts of the fifth metacarpals are also widened.

Figure 2 shows bilateral shortening of the fourth metatarsals which are also widened in comparison with adjacent metatarsals. Figure 3 demonstrates the widening of the diploic space of the calvarium.

A review of the patient's chart and film jacket revealed that she had been seen at age 11 months because of delayed development. Films of the hands and feet, now over 26 years old, show accelerated skeletal maturation (Figure 4). The skeletal age, as measured by the standards of Gruelich and Pyle,[5] is in the range of 18 to 24 months, being closer to the latter standard. Figure 5 demonstrates accelerated skeletal maturation at age 11 years.

Comment

The radiographic findings in this patient are virtually specific for the diagnosis of pseudohypoparathyroidism. Shortened metacarpals and metatarsals may also be found in myositis ossificans progressiva, hereditary multiple exostoses, multiple epiphyseal dys-

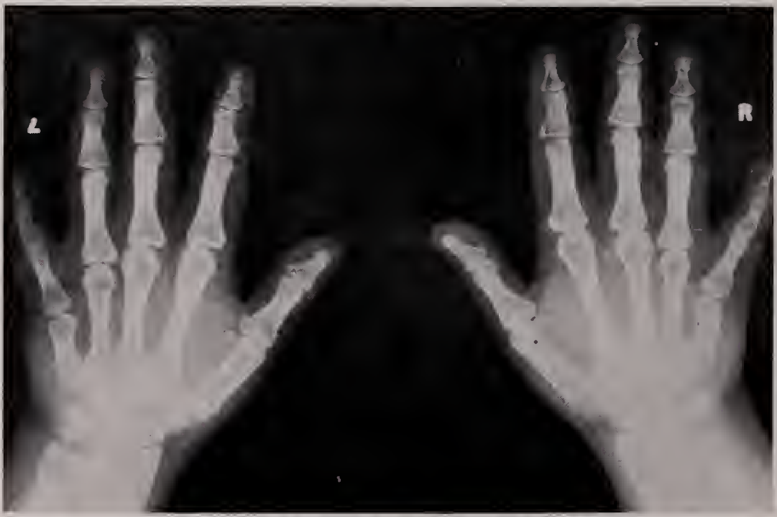

Fig. 1 — Age 27 years. Bilateral shortening and widening of the fifth metacarpals. Shortening of the fourth metacarpals.

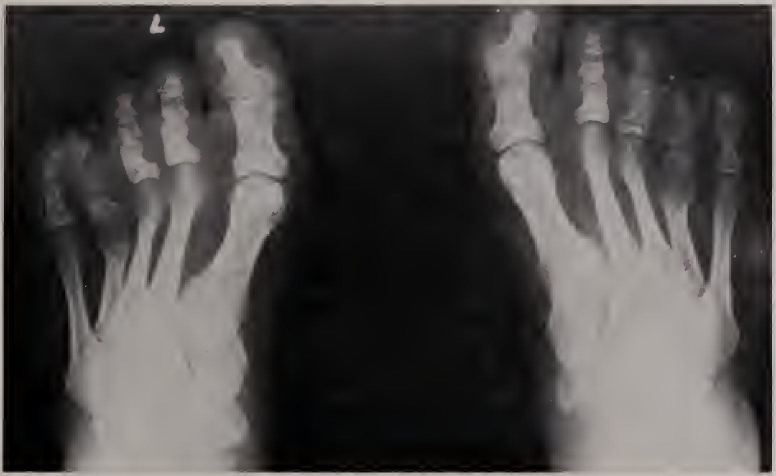

Fig. 2 — Age 27 years. Bilateral shortening and widening of the fourth metatarsals.

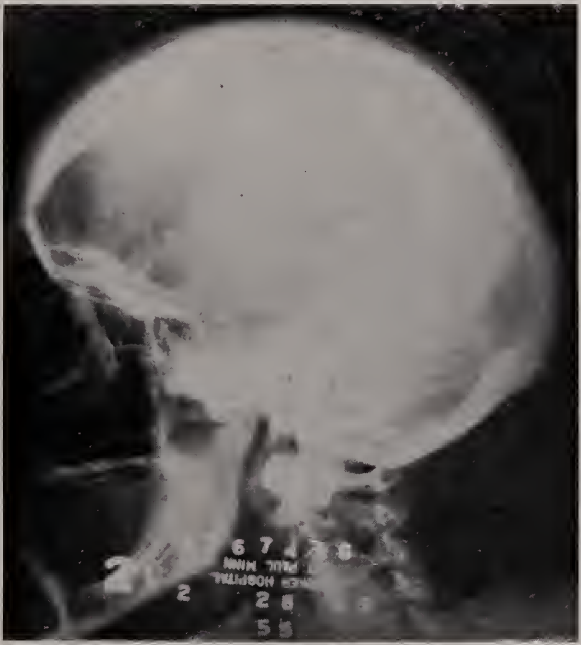

Fig. 3 — Age 27 years. Thickening of the calvarium due to widened diploic space.

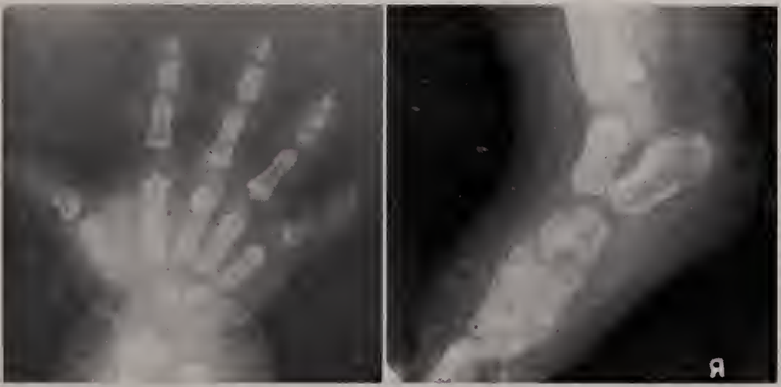

Fig. 4 — Age 11 months. Accelerated skeletal maturation is evident with the mean skeletal age estimated at 24 months.[5]

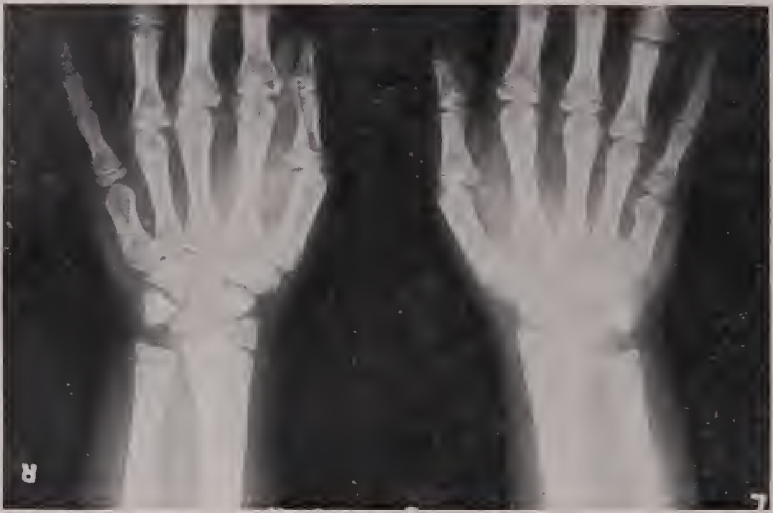

Fig. 5 — Age 11 years. Bilateral shortening and widening of the fifth metacarpals is evident. The epiphyses for the fifth metacarpals have closed.

plasia, and Turner's syndrome.[6]* However, thickening of the calvarium and accelerated skeletal maturation are specific among this group for the diagnosis of pseudohypoparathyroidism.

Except for the report of Cusmano,[4] there has been little emphasis on the finding of accelerated skeletal maturation. This was the earliest and most prominent finding in this patient, suggesting that pseudohypoparathyroidism must be included in the differential diagnosis of any child showing accelerated skeletal maturation.

Taitz[7] has described the case of a three-month-old infant with convulsions, tetany, hypocalcemia, and no response to a single intravenous dose of parathormone. The only radiographic finding was decalcification in the skull and long bones. Thus, the present patient represents (admittedly in retrospect) the earliest age of demonstration of the physical anomalies of this syndrome and also by far the longest follow-up of a verified case.

Mann[2] and Ray[8] explain the shortening of the metacarpals in this syndrome on the basis of premature closure of the epiphyses. However, Cusmano demonstrated shortening of the diaphyses during growth in his cases and stated that their metacarpal epiphyses did not fuse early. Our patient shows premature epiphyseal closure (Figure 5) ; however, the presence of widening of the shafts of the involved bones indicates a diaphyseal defect as well.

Because of the similarity in habitus and appearance of patients with hypothyroidism and pseudohypoparathyroidism, the former is frequently considered in the diagnostic work-up of these individuals. This patient represents the fifth documented case with both disorders.[9,10]

Summary

A case report is presented of a 27-year-old female exhibiting radiographic findings dating back to 11 months of age, the longest known follow-up on this syndrome. Accelerated skeletal maturation, thickening of the bony calvarium, and shortening of the metacarpals and metatarsals are emphasized in the diagnosis of this fascinating syndrome.

---

*See page 14.

We gratefully acknowledge the aid of David L. Hoffman, M.D., Section of Medicine, Mayo Clinic, Rochester, Minnesota, whose excellent diagnostic work-up on this patient provided the impetus for this report.

ALBRIGHT'S SYNDROME

(Polyostotic Fibrous Dysplasia)

This syndrome may be discovered because of incidental or accidental finding of fibrous dysplasia of the bone or because of sexual precocity or because of brown pigmented areas of the skin which may be observed in the course of a routine checkup. The syndrome is usually observed in children or young adults, predominantly in females. Hereditary factors may account for the bone cysts.

The multiple bone cysts consist of fibrous dysplasia which replaces the medullary structure. It is found more often in pelvic bones and the bones of the lower extremities. On occasion it may not be recognized until a pathologic fracture has occurred in childhood or early adult life.

The accompanying areas of cutaneous pigmentation vary in size from freckle-like birthmarks to large, flat, brown patches. The degree of pigmentation signifies the extent of skeletal involvement.

The endocrine features consist of unusual sexual precocity in the female with early onset of menstrual cycle, enlargement of breasts, and development of adolescent external genitalia. The 17-ketosteroid values are normal.

It may be necessary to differentiate this condition from hyperparathyroidism in which the bone lesions are generalized, whereas in Albright's syndrome a considerable portion of the skeleton is usually unaffected.

Pliny[†] on Dentifrices

Dentifrices in the days of Pliny were made from deer horns, unburned and reduced to powder, or from the pastern-bone* of an ox reduced to ashes and mixed with myrrh, or from the ashes of burnt pigs' feet, or the calcined bone of the cotylid cavities in which the hipbones move. As a matter of fact, the pastern-bone of a she-goat just killed, or of any other four-footed beast reared in the farmyard, the bone being reduced to ashes, was considered to make an excellent dentifrice. In some instances nard** was added as a corrective for bad breath. "Some persons, however, think it a better plan to mix the ashes of a mouse's head with the dentifrice."

---

*The phalanx of the ox though usually referred to the horse's foot.

**Used as perfume.

[†] See Minnesota Medicine, June 1964, page 716.

TURNER'S SYNDROME — (GONADAL DYSGENESIS)

The syndrome of ovarian dysgenesis is manifested typically by infantile development of secondary sex structures, short stature, and multiple congenital anomalies. Commonly associated anomalies are webbed neck, coarctation of the aorta, lymphedema of the extremities and skeletal, ocular and renal defects.

There may be iliac horns, dystrophy of the nails, anomaly of the patellae, and chondrodysplasia and arthrodysplasia, especially of the elbows. The iliac horns are occasionally found in routine roentgenograms and often indicate the presence of other abnormalities. Any one abnormality may occur independently of the others. Less constant abnormalities such as defects of the radial head, prominence of the acromion and clavicle, underdevelopment of the scapula, and discoloration of the iris have been reported.

Transmission occurs as a dominant hereditary character, and study of the genealogic tree of one patient revealed that 30 relatives in four generations exhibited these defects. (Senturia and Senturia).

Secondary sexual development is absent except for sparse pubic and axillary hair. The ovaries are replaced by a fibrotic ridge without evidence of either male or female germinal structures. A chromatin negative (male) sex-chromatin pattern is found in about 80 per cent of such patients. The typical finding in chromatin-negative gonadal dysgenesis is an XO sex chromatin constitution and a chromosome number of 45. In chromatin positive (female) dysgenesis two types of sex-chromatin abnormalities have been described: sex-chromatin mosaicism, and structural anomalies of the X-chromosome. Therapy is directed toward correction of the sexual infantilism and remediable congenital anomalies.

Grumbach, Melvin M.: Human Sex Anomalies from Cecil Loeb Textbook of Medicine, page 1421, Eleventh edition, W. B. Saunders, 1963.

WHAT'S YOUR DIAGNOSIS?

The patient was a clerk, age 30, intelligent, well educated. He had been ill for three months and was rapidly growing worse. Both hands were affected, the right more than the left. After writing for a short period of time the fingers would draw up in a cramped position, so that he could not use them. The fingers of both hands trembled a great deal, and he complained of severe numbness and shooting neuralgic pains in both. The index finger was very tender. He was unable to write a dozen lines, and yet he could paint and play the piano without difficulty. Prolonged effort to write produced cramps, jerking, and shaking, with the penmanship strokes becoming course and imperfect. A long rest of six months provided a cure.

What's Your Diagnosis? Turn to page 21.

If common sense has not the brilliancy of the sun, it has the fixity of the stars.

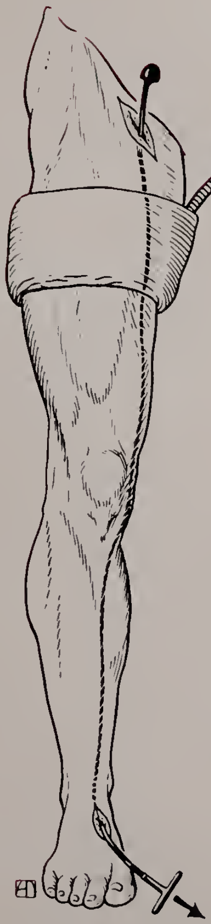
Remember there's always a voice saying the right thing to you somewhere if you'll only listen for it.—Thomas Hughes

Varicose Vein Stripping in Bloodless Limbs

REINHARD FISCHER, M.D.
ROBERT D. LORGE, M.D.
Wattwil SG, Switzerland



APPROXIMATELY TWO years ago a bloodless operating field in the extremity was obtained when doing vein stripping by the use of a pneumatic tourniquet. This was proved to be satisfactory.

Method

Under general anesthesia the blood is removed from the leg by applying a tight rubber Esmark bandage from the toes to the thigh. The leg is then kept bloodless by placing a sterile pneumatic tourniquet in the mid-thigh with a pressure of 550 mm. of mercury. The Esmark bandage is then removed and the usual stripping procedure is performed. The stripper can be passed under the tourniquet. If the operation lasts longer than 90 minutes, the tourniquet is released for 10 minutes. The tourniquet is finally removed after the skin incisions have been closed and the leg has been wrapped with an elastic bandage.

Results

After a period of two years, 190 patients with a total of 312 limbs have been stripped of their varicose veins. In 98 patients the operation was done without tourniquet and in 92 patients with the pneumatic tourniquet. In the 98 patients where the tourniquet was not used, 71 required blood transfusions.

With Tourniquet

Of the 92 patients operated upon with tourniquet, four patients required transfusions.

Duration

Duration of the operation was an average of 69 minutes in those where tourniquet was not used, and 76 minutes when tourniquet was applied.

Postoperative Complications

There were no postoperative complications of any significance, and in the tourniquet group there was a loss of sensitivity in the distal part of the limb in two subjects. This symptom disappeared within a few hours.

Comments

It has been our observation that the operation can be done more thoroughly and accurately in a dry field, and there is no difficulty in isolating the veins because they are previously marked. With severe arterial disturbance the use of the tourniquet is inadvisable.

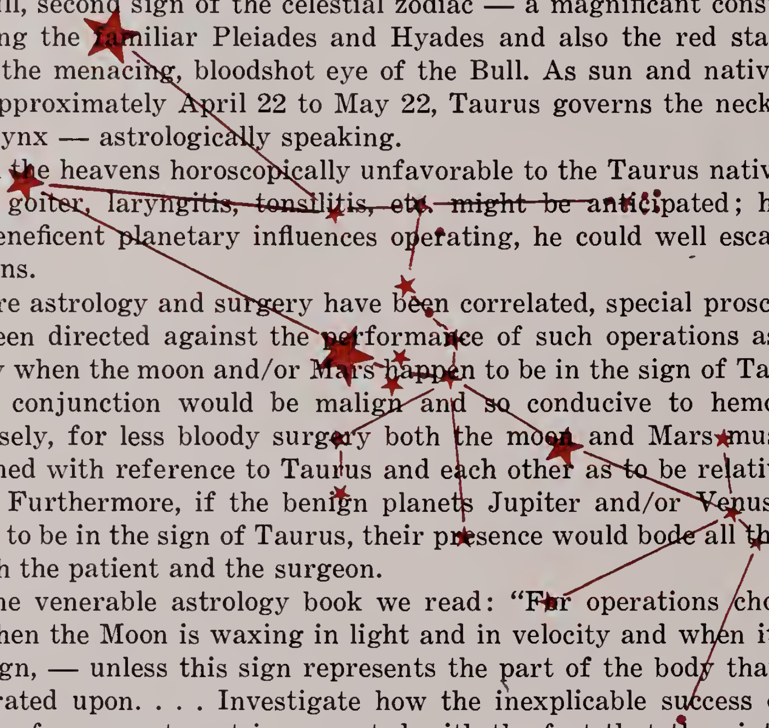
Astrology and Medicine — Taurus, the Bull



Brilliantly conspicuous in the southern January sky appears Taurus, The Bull, second sign of the celestial zodiac — a magnificant constellation including the familiar Pleiades and Hyades and also the red star, Aldebaran, the menacing, bloodshot eye of the Bull. As sun and nativity sign from approximately April 22 to May 22, Taurus governs the neck, throat and larynx — astrologically speaking.

With the heavens horoscopically unfavorable to the Taurus native, diphtheria, goiter, laryngitis, tonsillitis, etc. might be anticipated; however, with beneficent planetary influences operating, he could well escape such afflictions.

Where astrology and surgery have been correlated, special proscriptions have been directed against the performance of such operations as tonsillectomy when the moon and/or Mars happen to be in the sign of Taurus, as such a conjunction would be malign and so conducive to hemorrhage. Conversely, for less bloody surgery both the moon and Mars must be so positioned with reference to Taurus and each other as to be relatively impotent. Furthermore, if the benign planets Jupiter and/or Venus should happen to be in the sign of Taurus, their presence would bode all the better for both the patient and the surgeon.

In one venerable astrology book we read: "For operations choose the time when the Moon is waxing in light and in velocity and when it is in a fixed sign, — unless this sign represents the part of the body that has to be operated upon. . . . Investigate how the inexplicable success of some surgeons for a great part is connected with the fact that they intuitively choose the right time for their operations."*

Isolation of Candidate Viruses in Hepatitis*

E. E. MUIRHEAD, M.D.**
H. SCHNEIDER, M.D.**
Detroit, Michigan

Broad co-operative studies can improve our knowledge of hepatitis. Present laboratory methods are successful and need wider application.

HEPATITIS REPRESENTS the major unresolved problem in blood banking today, particularly since knowledge concerning antigens and antibodies, technics for their identification and the application of preservative anticoagulant solutions have expanded to a very practical level. In the area of hepatitis, there is not only the hazard to recipients of blood as a medical complication but there is also the hazard to professional personnel due to medico-legal implications. Yet, from a public health standpoint, infectious hepatitis appears to be more common (over 70,000 cases are recorded annually). While the incidence of transfusion hepatitis remains uncertain, it appears to be considerably less than that of infectious hepatitis.

From the standpoint of this discussion, distinctions between infectious hepatitis due to Type A virus and transfusion hepatitis due to Type B virus will not be made since the technics to be mentioned are not able to make the distinction. From an investigative standpoint, information derived with respect to one viral agent will likely have a bearing on the other.

Candidate Agents

Primary emphasis is being placed on the isolation of candidate agents in hepatitis by several laboratories over the country. The candidate virus is one which is suspect as causative toward a disease. A number of such candidates have been reported in hepatitis. Most candidates at the moment are being derived by means of tissue culture technics. There are difficulties here, including 1) the fact that isolation of a transmissible agent in vitro does not imply an etiologic position, and 2) duplication of results in different laboratories has been difficult although some of these problems are being resolved.

---

**Department of Pathology and Blood Bank, Woman's Hospital and Wayne State University School of Medicine, Detroit.

Suitable Tissue for Culture

The hepatitis program at Wayne State University in Detroit has been directed primarily toward the development of a reliable technic for preparing primary cultures from various tissues suitable for propagating hepatitis candidates. By primary culture is meant a tissue culture from a normal source which can be reproduced, de novo, repeatedly from the original source and which is, at the same time, sensitive to candidate viruses of hepatitis. This term "primary" is used in contradistinction to an established cell line which is repeatedly transferred. In this connection, the reference tissue culture has been the Detroit-6Y (D-6) cell line first isolated by Stulberg and Berman from a patient having a malignant disease and used effectively by Rightsel, McLean and associates at the Parke, Davis Company. The Detroit-6Y line is an established cell line. It has been possible to maintain the line of Detroit-6Y cells highly sensitive to hepatitis candidates. In addition, cultures prepared from normal canine lung have shown great promise as means of transmitting the hepatitis candidates.

Library of Serums

The Wayne State University program has included a collection of serum from over 800 cases of hepatitis having classical, clinical expression including jaundice and evidence for self-limited, acute hepatocellular injury (elevated transaminase, thymol turbidity, gamma globulin, etc.). Acute and convalescent serums have been obtained from most cases. This library of serums is kept frozen and is being evaluated for candidate viruses as time allows.

Thus far, serum from over 120 cases has been evaluated for transmissible agents in tissue culture and has been found to be positive. The agents so recovered are stored in the frozen state. The harvesting of so many agents raises an obvious question, namely, the need for classification of the agents in order to determine whether few or many strains are involved. Already there is some indication that multiple strains pertain. Moreover, several laboratories have collected their own groups of candidate viruses. At present, a general attempt to classify these various agents appears most appropriate and germane. Unfortunately, the technics for classification are not simple and rest primarily on in vitro neutralization tests.

For the purposes of considering certain approaches used at Wayne State University, two major candidate viruses for hepatitis which we have isolated will be reviewed briefly. The cases from which these agents were recovered as well as a detailed account of the agents will be presented elsewhere.

Specific Agents

Several laboratories now have available cell lines which appear reasonably stable and sensitive to transmissible agents which can be derived from patients having hepatitis. Moreover, some laboratories at last are duplicating results from other laboratories. For instance, the two agents we are about to consider have been studied with comparable results at a preliminary level at two laboratories other than our own. The indications are then that with proper collaboration between research laboratories, it should be possible to delineate further the characteristics of the agents and to begin to consider more effectively the classification of different strains. Once pure agents are available, then the matter of more specific diagnostic tests can be tackled.

The technics at Wayne State University are well known classical tissue culture technics as applied to the recovery of viral agents. This includes the growth of monolayer cultures, the prevention of contamination with bacteria and fungi, and the demonstration of cytopathogenic effect as an index of positive growth of the transmissible agent or virus. Naturally, it must be demonstrated that the cytopathogenic effect is not due to a toxic ingredient used in the culturing technic. Thus, repeated cultures, repeated testings for contamination, and repeated testings for toxicity are necessary routines.

Concerning the technics of growth of cells sensitive to candidate agents in hepatitis, it was found that the cell line must be inspected daily and the media replenished as needed. The pH of the media is followed closely and the media is changed when the pH drops to 6.5. The cells are transferred at least twice a week and inoculated at approximately 80-100,000 cells per ml., thus keeping the tissue culture in the log phase of growth. The cell lines are handled in separate hoods which are used exclusively for a given cell line. This precaution became essential after five different cell lines were studied by R. R. A. Coombs for mixed agglutination. Three of the animal cell lines were found to be contaminated with human cells. A small hood was developed which prevented cross-contamination even after sixty transfers, as confirmed by chromosome studies.

Figure 1 shows a monolayer culture of Detroit-6Y cells prior to inoculation with a potential candidate material. The cells grow as a normal-appearing epithelial line (picture taken through a glass bottle). Figure 2 demonstrates the typical cytopathogenic effect. The cells have pulled away from each other, forming clear areas in the culture. At the same time, cells show definitive changes characterized by rounding of the cytoplasm, clumping of cells and alterations of nucleus.

Candidate Virus OE

The first exemplary case to be considered culminated in the isolation of dioxyribonucleic virus in the case of infectious hepatitis from serum and liver tissue of the patient. The agent has been labelled candidate virus OE after the initials of the patient, a 70-year-old white male who suddenly developed weakness, anorexia, chills, fever, nausea and vomiting ten days after moderate acute upper respiratory illness. He developed jaundice and within less than 36 hours was mentally confused and comatose. Liver function tests indicated severe hepatocellular damage, the coma worsened and the patient died. At autopsy, the liver was typical for acute yellow atrophy. Microscopically, there was also complete necrosis of the liver associated with collapse fibrosis, focal hemor-

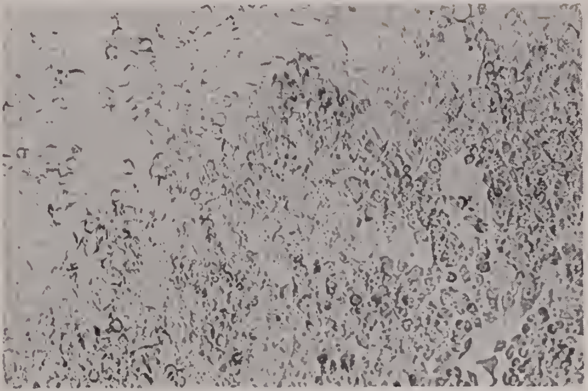

Fig. 1 — Regular (uninoculated) culture of Detroit-6 cell line, D_6Y clone.

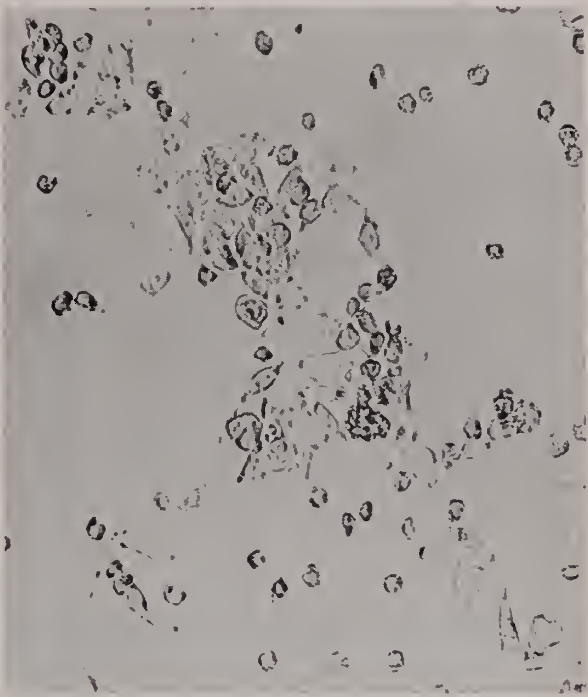

Fig. 2 — Cytopathogenic effect on D_6Y cell line as evoked by hepatitis candidate virus.

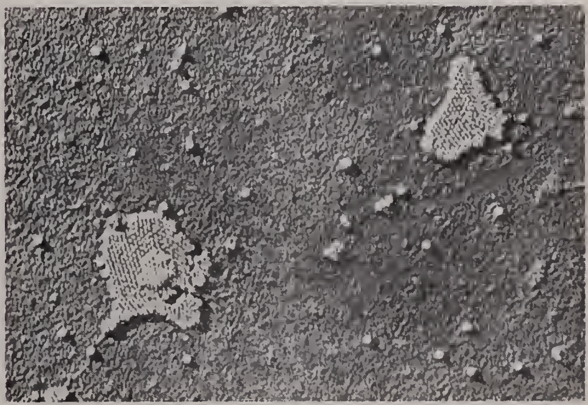

Fig. 3 — Viral-like particles from genetron extract of OE liver (electronmicroscopy by Dr. A. R. Taylor, Parke, Davis Company).

rhages and bile stasis. Other than hepatic findings, the patient exhibited only bronchopneumonia.

The tissue culture cells used for isolation purposes in this case consisted of a clone of Detroit-6Y cells which had been passed approximately 160 times and had retained uniform sensitivity to control hepatitis virus isolates of the candidate type. This particular cell line shows characteristic cytopathogenic effect within eight to 10 days. The control viruses were proved to be of hepatitis type by inoculation into normal volunteers as conducted by Boggs and the Parke, Davis Company.

The patient's acute phase serum was heated to 60° C for 30 minutes, then diluted 1:10, 1:20 and 1:40 in maintenance media and placed on the Detroit-6Y cells for primary isolation. Figure 1 shows representative cytopathogenic effect produced by this serum. These initial isolates were harvested and passed three times in Detroit-6Y cells and then stored for future study at −20° C.

Viral extracts were obtained from 2 gm. of candidate virus OE liver and from serum, using a modification of the Gessler method (fluorocarbon extraction). Aliquots of the supernatant from the genetron (fluorocarbon extraction) were used for virus isolation, nucleic acid identification and electronmicroscopy.

The extract was treated as a viral isolate and dilutions of 10^{-1}, 10^{-2}, 10^{-3} and 10^{-4} were made of material unheated and heated at 60° C in a water bath. Detroit-6Y cultures were inoculated. At seven days, typical cytopathogenic effect was noted. The extract of serum and of liver gave the same results. The 10^{-3} dilution was passed in the Detroit-6Y cells and subsequent titration of this second passage yielded a positive cytopathogenic effect through the 10^{-10} dilution, suggesting a major replication of the transmissible agent.

Two aliquots of the supernatant from the fluorocarbon extraction were treated with cold phenol. This phenol extract was subsequently treated with RNAse and DNAse and tested in the sensitive Detroit-6 cells. RNAse alone added to the maintenance media gave negative results (no cytopathogenic effect). The candidate virus OE nucleic acid plus DNAse gave negative results indicating that the material causing results originally was a dioxyribonucleic type virus. Conversely, the candidate virus OE nucleic acid subjected to RNAse gave positive results indicating that the material was not ribonucleic acid and by inference supported its dioxyribonucleic makeup.

A sample of the genetron supernatant was diluted 200 times in 0.1 normal Ringer's solution and subjected to electronmicroscopy

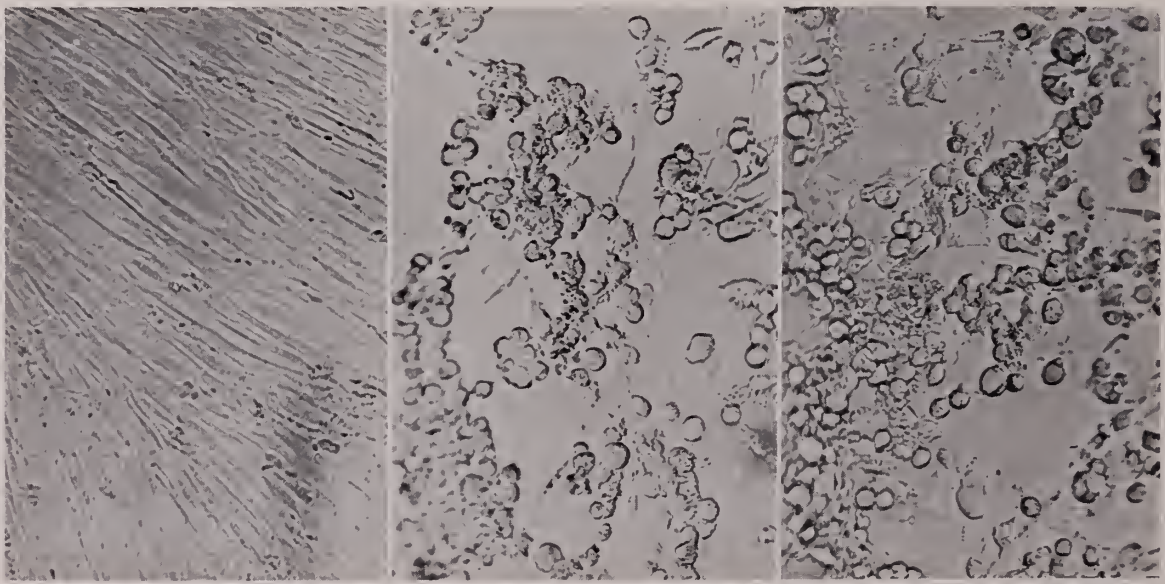

Fig. 4 — Canine lung cell line. Panel on extreme left represents uninoculated normal culture; the other two panels display CPE of canine line due to the RG agent.

by Dr. A. R. Taylor of Parke, Davis. Figure 3 shows representative viral particles from the candidate virus OE liver extract as derived by chrome shadowing.

In summary, patient with candidate virus OE exhibited a clinical and laboratory picture compatible with infectious hepatitis and acute yellow atrophy. The acute yellow atrophy was confirmed in autopsy. The serum from the patient as well as an extract of the hepatic tissue produced virus-like isolates which yielded typical cytopathogenic effect on Detroit-6Y cells indistinguishable from the cytopathogenic effect produced by control hepatitis virus as identified in a volunteer study conducted by Boggs and the Parke, Davis group. Further, the candidate agent appeared to be of dioxyribonucleic type.

Candidate Virus RG

The second agent we wish to consider was derived from a case of chronic hepatitis occurring in a young woman. This agent contrasts sharply in several respects with the candidate virus OE agent and therefore appears to be of a different strain. In addition, the agent has yielded interesting results with a primary cell line derived from the canine lung. The agent was derived repeatedly from the patient's serum. It has been designated as candidate virus RG from the initials of the patient.

The patient was first seen in 1959 at age 16 because of jaundice, light-colored stools, lassitude, epigastric pain. The liver was enlarged and tender. The laboratory findings included a serum bilirubin of 6 mg.%, and serum protein of 11 gm.% with 7 gm. of globulin. Three months later, the patient was readmitted with amenorrhea, arthritis, chills and fever. The bromsulphalein test was elevated and transaminase was greater than 500. Serum electrophoresis showed a total protein of 11.5 gm. with 8 gm. of gamma globulin of the broad base or polyclonal type. Biopsy of the liver was interpreted as showing chronic hepatitis or postnecrotic cirrhosis.

Candidate virus RG serum yielded positive cytopathogenic effect on the Detroit-6Y line. Figure 4 shows results with a primary canine lung line. The panel in the extreme left shows the appearance of the normal control canine line (uninoculated with candidate material). It grows as a fibroblastic line. The other two panels show the typical cytopathogenic effect as derived from the RG agent. There is rounding of the cells, clumping, and a characteristic ballooning effect of the cytoplasm due to vacuolization. Electronmicroscopy study of these cells conducted by Dr. Taylor showed particles within the cytoplasm which resembled viral particles. Earlier, there was some suggestion that the candidate virus RG agent resembled canine hepatitis virus and therefore may have activated a latent virus in the canine lung cells. Subsequent work has not supported this view. Thus, the candidate virus RG agent is considered as a candidate virus in hepatitis. It is unique in its characteristics in tissue culture as well as in its origin from a case of chronic liver disease in a young woman having the characteristics of the Bearn-Kunkel syndrome.

The types of observations made with the candidate agents OE and RG are similar to observations being made in different laboratories in this country. These include the recovery of viral-like agents from cases reflecting different types of hepatitis as well as from primates. Thus, the tools appear available for a fundamental elucidation of the etiology of hepatitis. These, however, need to be sharpened and there is additional need for a considerable amount of co-operative work at the level of interchange of information, technics and specific agents recovered.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 14)

This case was described by G. Durant Hood, M.D. in 1901 as being writer's cramp. It sounds like nothing in this modern age. What is your diagnosis?

Carpal Tunnel Syndrome*

DONALD M. YAMAGUCHI, M.D.**
PAUL R. LIPSCOMB, M.D., F.A.C.S.***
EDWARD H. SOULE, M.D.†
Rochester, Minnesota

COMPRESSION NEUROPATHY of the median nerve in the carpal tunnel has been referred to by terms such as "acroparesthesia of the hand," "writer's cramp," "occupational neuritis," "partial thenar atrophy," "thenar palsy," "median neuritis," "median thenar neuritis," "tardy median palsy," and "carpal canal disease." This condition has become known as "carpal tunnel syndrome" because of the many causative factors, and controversy still exists concerning its etiology and pathogenesis. A clinicopathologic study was undertaken at the Mayo Clinic to determine the pathogenesis of this condition.

Material and Methods

This study is based on a review and analysis of data from 1215 patients with carpal tunnel syndrome seen at the Mayo Clinic from 1930 to 1960. These patients were seen from a few days to many years after the onset of symptoms. Eighty-four of the cases have been reported previously. Of the 1215 patients, 756 were treated nonsurgically or were observed after the diagnosis was made, and 459 patients were treated surgically. For the latter group, biopsy specimens and sections of tissue from 204 hands of 177 patients were available for study. The tissue sections were stained routinely with hematoxylin and eosin and in selected cases with a methyl violet stain for amyloid deposits. Several histologic sections from each specimen were studied.

The histories of all patients having carpal tunnel syndrome were reviewed carefully. Follow-up letters were sent to those who had been treated by surgical decompression, if follow-up studies were incomplete.

Controlled studies of the histologic material were based on gross and microscopic sections of the flexor synovialis and transverse carpal ligament obtained from upper extremities amputated because of malignant lesions.

Clinical Findings

Pertinent data concerning the age, sex and involvement of the hand are shown in Table 1.

The duration of symptoms before the patients were seen at this clinic varied from a few hours to forty years.

Categorization of the patients according to their occupations was somewhat difficult

Surgical correction of the compression found in "Carpal Tunnel Syndrome" provides relief from symptoms and prevents progression of the disease. Sensory and motor nerve loss can be prevented.

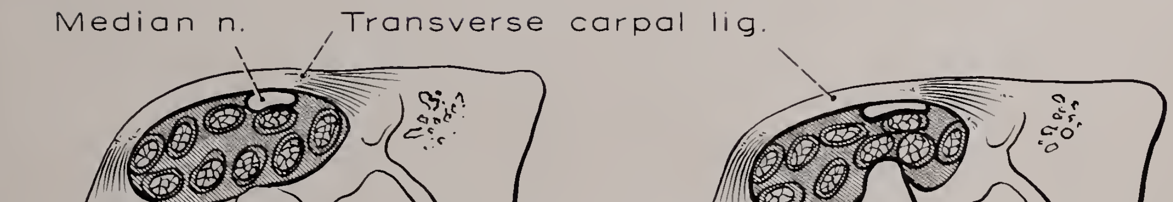

Fig. 1 — Mechanisms whereby the median nerve may be compressed in the carpal tunnel. (a) Normal relationship of the median nerve to the nine flexor tendons, tendon sheaths and transverse carpal ligament. (b) Encroachment of bone into the tunnel producing secondary compression of the nerve. (c) Thickening of the tendon sheaths (flexor synovialis) producing compression of the nerve. (d) Foreign bodies, tumors and other space-occupying lesions in the carpal tunnel producing compression of the nerve.

because many housewives had part-time jobs that were not listed in the clinical history (Table 2). Housewives (50.8 per cent) composed the largest occupational group; professional and sedentary workers (28.3 per cent) were the second largest group. Table 2 also shows the distribution of patients treated by surgical and nonsurgical methods.

Symptoms and Tests

Symptoms and signs of carpal tunnel syndrome are related to irritation, compression, or impairment of function of the median nerve at the wrist. The commonest symptoms were paresthesias (99 per cent of the 433 surgical patients); atrophy or weakness of the thenar muscle was noted in at least half of the patients. Electromyography proved to be of greatest value in our cases. The pneumatic-cuff test was performed in a few cases but was not helpful.

Associated Diseases and Trauma

Systemic diseases existed in 26.2 per cent of the 1215 patients, rheumatoid arthritis in 7.7 per cent, and myxedema in 6.3 per cent (Table 3). However, of the 318 patients with known systemic diseases, more than half (53.5 per cent) had rheumatoid arthritis or myxedema. Six had acromegaly. Sarcoidosis, polymyositis, syphilis, alcoholism, and neurofibromatosis were the only associated diseases in our series which had not been reported previously by other authors.

So-called rheumatic conditions were present in 237 or 19.5 per cent of our patients (Table 4). More than half (51.1 per cent) in this group had periarthritis of the shoulder. Traumatic conditions of the wrist were present in 161 or 13.2 per cent. More than half of this group had a history of Colles' or carpal navicular fractures; two had lunate dislocations; 66 had degenerative arthritis of the wrist not related to rheumatoid or other arthritis, and one had a hematoma of the wrist. Roentgenograms were made of 697 of the 1215 patients, and degenerative arthritis of the cervical portion of the spinal column was proved in 438 patients. Twenty-one were found to have asymptomatic cervical ribs. Eighteen had previously undergone operation elsewhere, eleven for carpal tunnel syndrome and seven for scalenotomy or cervical rib resection. One patient had a giant cell tumor on the distal portion of the radius.

TABLE 2
Classification of Patients by Occupation and Method of Treatment

Occupation	Surgical group	Nonsurgical group	Total Number	Total Per cent
Housewives	191	315	506	41.6

Laborers (mechanics, carpenters, factory and construction workers, and common laborers)	43	61	104	8.6
Miscellaneous (waitresses, cooks, janitors, maids, bartenders)	14	44	58	4.8
Total	459	756	1215	100.0

Etiologic Aspects

Normally there is little room in the carpal canal, and any pathologic distortion of the wall or any conditions which increase the volume of the contents of the canal may produce carpal tunnel syndrome.

Commonly, the flexor synovialis becomes thickened owing to tenosynovitis associated with rheumatoid arthritis, gout, tuberculosis, pyogenic infections, myxedema, pregnancy, acromegaly and amyloidosis; but in the majority of cases carpal tunnel syndrome is due to nonspecific thickening of the tendon sheath. The altered relationship of structures in the carpal canal is illustrated schematically in a diagram similar to one prepared by Michaelis (Fig. 1).

Pathologic Findings

We compared the microscopic findings in specimens of the flexor synovialis removed from patients having carpal tunnel syndrome with similar specimens removed from amputated upper extremities of patients who, to our knowledge, had no history suggestive of carpal tunnel syndrome.

Specimens were obtained from a control group of fourteen patients whose ages varied from eleven to seventy-two years. Four were in the second decade, two each in the third, fourth, fifth, and sixth decades, and one each in the seventh and eighth decades.

No abnormality of the transverse carpal ligament was found in any of these specimens.

The test group of specimens consisted of tissue removed at the time of operation from 204 hands of 177 patients with carpal tunnel syndrome. There were twenty specimens of transverse carpal ligaments, and 204 specimens of flexor synovialis. Specimens from both wrists were not always removed from patients who had bilateral involvement.

Gross Observations.

Grossly, specimens from the controls exhibited a cloudy-white, nontransparent flexor synovialis of variable thickness in the older age group, whereas, in the younger age group this structure consisted of an extremely thin, glistening white, transparent membrane. The median nerve was not abnormal in any way in any of the fourteen controls.

In the test group gross examination of the median nerves at the time of operation showed them to be normal or flattened and constricted. At the point of constriction, the nerve was often hyperemic and there was increased fibrosis of the perineurium. Proximal to the constriction, there was apt to be

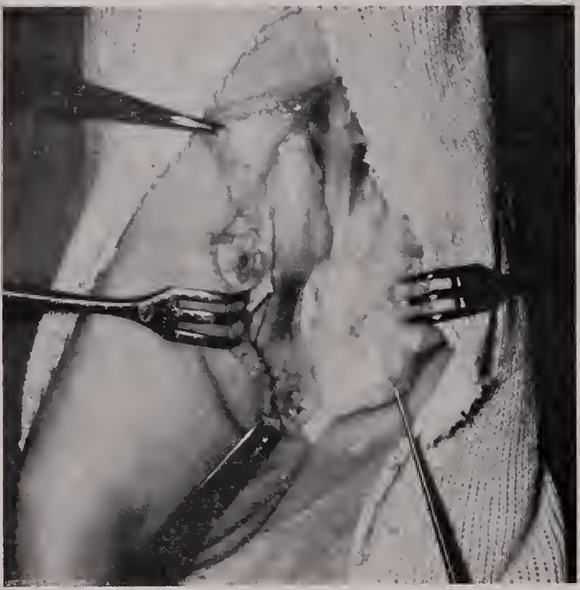

Fig. 2 — Note the severe constriction of the median nerve in a patient with long-standing carpal tunnel syndrome due to thickened flexor synovialis. A neuroma had formed proximal to the point of constriction. Hyperemia had also developed at this point. Thenar atrophy and sensory loss were present in this patient. (From Lipscomb, P. R.: Tenosynovitis of the Hand and the Wrist: Carpal Tunnel Syndrome, de Quervain's Disease, Trigger Digit. Clin Orthop 13:164, 1959).

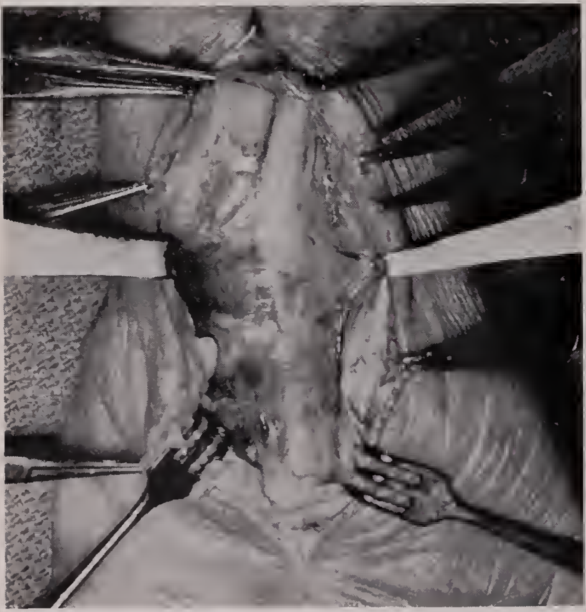

Fig. 3 — Exposure of the median nerve in the carpal tunnel. The flexor synovialis is grossly inflamed and thickened. The increased vascularity, the edema of the synovia and the crowding within the carpal tunnel completely obscure the flexor tendons.

fusiform enlargement of the nerve. The flexor synovialis was thickened, cloudy white, nontransparent and lusterless; variable amounts of edema and fluid were present. If inflammation was present, the synovialis appeared gray, thickened, hyperemic, and edematous and an increased amount of fluid was present (Fig. 2 and 3).

Microscopic Observations

Microscopically, the control group of specimens showed the presence of one to five layers (depending on the age group) of flattened endothelial-like cells in the synovium (Fig. 4 and 5). Next appeared a layer of subsynovial tissue (zone 2) (Fig. 4 and 5), which consisted of loose areolar tissue having few capillaries, and then a dense layer of collagenous, fibrous tissue with scattered fibroblasts and arterioles (zone 3). Usually a layer of fatty tissue was present at the periphery (zone 4).

In the older age group, zone 1 was as thick as five cell layers, while zones 2 and 4 remained about the same in thickness, depending somewhat on the obesity of the patient. Zone 3 showed the greatest difference in the controls. In the older age group the degree of fibrosis and thickness of the vessel walls was increased. Rarely were inflammatory cells present in any of the four zones.

Histologic Grading

For the most accurate comparison of the findings in the controls with those in the test specimens removed from surgical patients, a more detailed list of factors was examined. Histologic sections were evaluated by rating the relative presence or absence of ten factors. Each factor was graded from 0 to 4: zero indicated an absence of the factor, grade 1 slight presence, grade 2 moderate presence, grade 3 rather definite presence, and grade 4 considerable evidence of the factor.

The ten factors studied in the varying zones were as follows: *zone 1:* (1) synovial layer (number of cell thickness), (2) synovial folds or villi; *zone 2:* (3) quantity of subsynovial capillaries, (4) amount of edema; *zone 3:* (5) quantity of subsynovial capillaries and arterioles, (6) thickness of walls of blood vessel, (7) degree of subsynovial fibrosis; *zone 4:* (8) amount of adipose tissue; and in *zones 1 to 4:* (9) inflammatory cells (lymphocytes, plasma cells, monocytes and polymorphonuclear leukocytes) and (10) amount of perivascular inflammatory cells.

Pathologic findings were classified in two main categories: (1) well-defined, or (2) ill-defined and not fitting into the pattern of any previously described entity.

In the group in which the pathologic findings were well-defined, twenty-two patients had specimens compatible with a diagnosis of rheumatoid tenosynovitis: two with gouty tenosynovitis and one each with lipoma, neuroma (following previous operation), suture granuloma, amyloidosis, nonspecific granulomatous tenosynovitis, tuberculous tenosynovitis and an isolated bony ossicle (Fig. 6 and 7). The etiology of the carpal tunnel syndrome in these patients was easy to establish and therefore no further elaboration is required. This group composed only 17.5 per cent of the 177 patients whose tissue was analyzed. Carpal tunnel syndrome in 12.4 per cent of this group was due to rheumatoid tenosynovitis.

The specimens from 146 patients fell into the category of ill-defined findings with a pattern that did not fit any previously described entity; specimens from the 146 patients (71.8 per cent) were thought to show nonspecific tenosynovitis and were classified according to microscopic findings into the following four subgroups.

Subgroup 1

Nineteen patients (10.7 per cent of 177) with findings similar to the control group were called "normal" and compared favorably with the control group (Fig. 5).

Subgroup 2

Sixty-two patients (35 per cent) with findings only slightly more significant than those of subgroup 1 showed a slightly greater amount of fibrosis and edema; occasionally inflammatory cells were noted (Fig. 8*a*).

Subgroup 3

Forty patients (22.6 per cent) in whom the findings differed greatly from those in subgroups 1 and 2: zone 1 was thickened and consisted of six to ten cell layers, zone 2 was much more vascular, zone 3 showed an increase in fibrosis and thickened vessel walls. Inflammatory cells were present in moderate amounts in nearly all zones but especially in zones 2 and 3 (Fig. 8*b*).

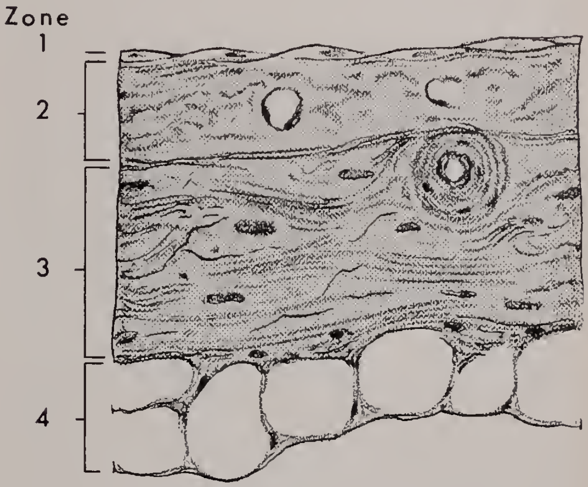

Fig. 4 — Diagram of normal histologic section of the flexor synovialis. The tissue layers are denoted as zones: zone 1, endothelial-like cells; zone 2, loose areolar tissue; zone 3, fibrous tissue with scattered fibroblasts and arterioles; and zone 4, fatty tissue.

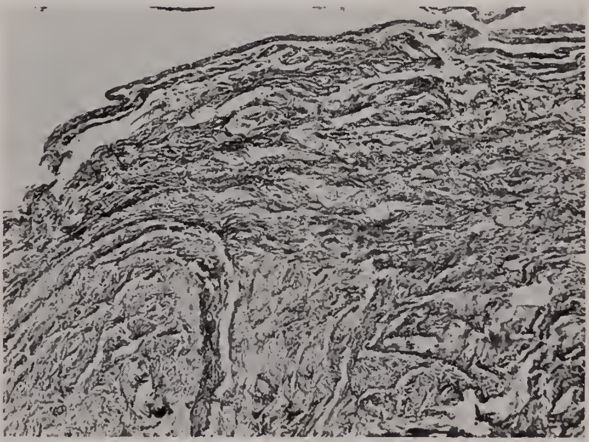

Fig. 5 — Section of the flexor synovialis of a twenty-nine-year-old person from the control group. The synovial membrane is two cell layers thick, beneath which is rather avascular subsynovial fibrous tissue (hematoxylin and eosin; magnification x95 before reduction).

Subgroup 4

Twenty-five patients (14.1 per cent) with severer findings than those in subgroup 3: zone 1 was greatly thickened and was often infiltrated with inflammatory cells. In certain areas the cell reaction and vessels were so numerous that the tissue simulated a hemangioma or granulation tissue (Fig. 8*c* and 9).

Diagnosis

The following factors should be considered in the diagnosis of carpal tunnel syndrome: (1) a history of paresthesias in the distribution of the median nerve, (2) a history of major trauma, (3) a history of associated systemic diseases or conditions, (4) objective sensory impairment in the distribution of the median nerve, (5) weakness or atrophy of the thenar muscles, (6) localized swelling proximal to the distal wrist crease, (7) tenderness or tenseness in the region of the transverse carpal ligament, (8) vasomotor or trophic changes in the hand, (9) positive results to the wrist flexion test of Phalen, (10) positive Tinel sign, (11) positive results to the tourniquet test of Gilliatt and Wilson, and (12) amelioration of symptoms with immobilization of the wrist in the neutral position by light plaster-of-paris splint and by the injection of hydrocortisone into the carpal canal.

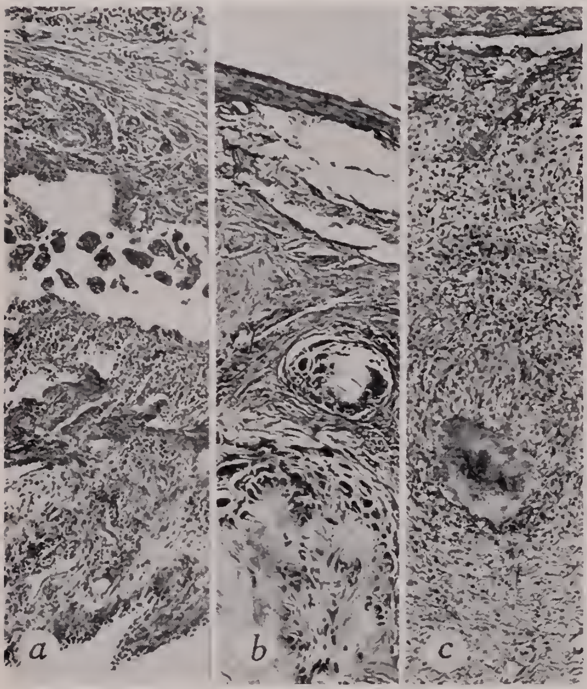

Fig. 6 — Specific types of tenosynovitis: (a) Section of the flexor synovialis from a sixty-year-old woman with rheumatoid tenosynovitis. Note the definite villous formation and the diffuse infiltration of inflammatory cells about the vessels and in the subsynovial tissue (hematoxylin and eosin; magnification x65 before reduction). (b) Section of the flexor synovialis from a patient having gouty tenosynovitis. Note the thin synovial layer on the top and the uric acid deposit on the bottom surrounded partly by foreign body giant cells (hematoxylin and eosin; magnification x100 before reduction). (c) Section of the flexor synovialis from a twenty-seven-year-old man with nonspecific granulomatous tenosynovitis. Note the giant cell in the center of the granuloma (hematoxylin and eosin; magnification x100 before reduction). Tissue cultures for fungi and tubercle bacilli were negative.

Laboratory Aids

Aids to establishment of a diagnosis include electromyography with delayed conduction time in the fibers of the median nerve across the carpal tunnel (Fig. 10) and roentgenograms to show whether evidence of degenerative arthritis, old fractures, extra ossicles, or other changes appears at the wrist joint. Myxedematous patients show a decrease in protein-bound iodine, radioactive uptake, and basal metabolic rate. Patients with rheumatoid arthritis may have an increase in the erythrocyte sedimentation rate and a positive rheumatoid factor.

Evidence of Nerve Damage

Although thenar atrophy and paresthesias and sensory loss in the distribution of the median nerve can each occur with other disease entities, this combination of symptoms and signs is unlikely to be found in nontraumatic conditions other than carpal tunnel syndrome.

Paresthesias in the fingers due to protruded cervical disks or cervical spondylosis are generally accompanied by radicular features and associated with pain and limited motion in the neck.

In our series of 1215 patients, an interval of two weeks to twenty years was noted between the onset of involvement in the dominant hand and the involvement of the other hand.

Treatment

Marie and Foix in 1913 first suggested treatment of the carpal tunnel syndrome by sectioning of the transverse carpal ligament. This was first carried out in 1941 on a patient at the Mayo Clinic.

Surgical Decompression

Longitudinal section of the transverse carpal ligament is still the treatment of choice for most patients with appreciable trouble from carpal tunnel syndrome. General anesthesia, axillary block, or local anesthesia may be used for the procedure. A bloodless field is provided by the use of a tourniquet on the upper part of the arm. The section is always carried to the ulnar side of the nerve. It is advisable (as advocated by Phalen) to section the palmaris longus tendon and to allow it to retract upward.

Of the 459 surgical decompressions in our series, 62.7 per cent of the patients had bilateral operations; 24.2 per cent had operations on the right hand only, and 13.1 per cent on the left hand only. *Neurolysis* usually was performed if the median nerve was constricted. Hydrocortisone was injected into the carpal tunnel in most cases at operation. Ninety-six per cent of the patients had good sensory recovery and 50 per cent had improvement in thenar muscle function after operation, the degree of sensory and motor recovery depending on the duration of symptoms and the severity of involvement. In general, sensory recovery was good, with improvement over a period of months. If thenar atrophy had been present for longer than a few weeks there was little recovery of motor function.

Desiccated Thyroid

Patients with myxedema generally responded to conservative treatment with desiccated thyroid; but surgical decompression was performed on eight of seventy-seven patients with myxedema because of progressive and incapacitating symptoms and weakness of the thenar muscle.

Splinting

Splinting of the wrist in patients with nocturnal symptoms who had no objective sensory loss or thenar atrophy was efficacious in a number of patients. Hydrocortisone injected into the carpal canal also gave temporary relief of symptoms early in the course of the syndrome.

It was noted that symptoms of the carpal tunnel syndrome which appeared in the last trimester of pregnancy usually subsided spontaneously within a few weeks or months after delivery. Of the twenty pregnant women suffering from this syndrome in our series, only one needed surgical decompression. This was carried out four days after delivery because of objective loss of sensation and severe paresthesias in the distribution of the median nerve.

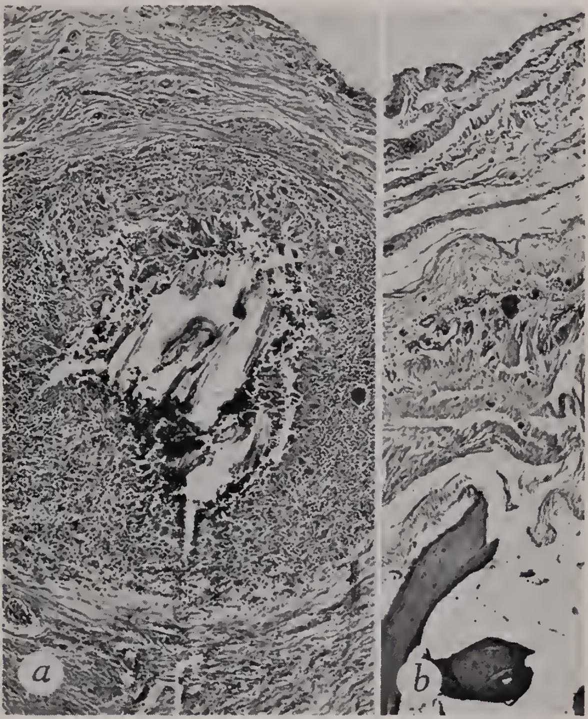

Fig. 7—(a) Section of the flexor synovialis from a fifty-seven-year-old woman who had had a previous surgical decompression elsewhere six months previous to coming to the clinic for carpal tunnel syndrome and who had recurrence of symptoms. Note the focal, subacute, and chronic microabscesses with foreign body giant cell and suture material (hematoxylin and eosin; magnification x70 before reduction). (b) Section of flexor synovialis from a fifty-seven-year-old man who had tenosynovitis and carpal tunnel syndrome due to an osseous body lying in the carpal canal. Note the slightly thickened synovium at the top on the left and the osseous trabeculae at the bottom (hematoxylin and eosin; magnification x50 before reduction).

Results

At the time of this report the recurrence of symptoms after operation in our series has been very low. Only three of the patients on whom we operated have required more than one operation on the wrist; eleven others had had surgical decompression performed previously elsewhere. Thirteen patients were thought to have had inadequate decompression at the time of the first operation, and the recurrences may have been due to inadequate sectioning of the distal fibers of the transverse carpal ligament. A wound infection developed in one of our patients after the first surgical procedure, and at the second operation the nerve was found in dense scar tissue which no doubt resulted from the infection. This patient obtained excellent relief of symptoms after neurolysis.

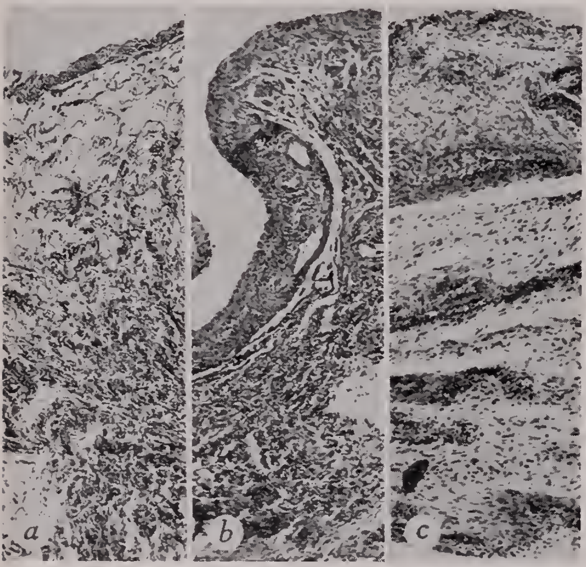

Fig. 8—(a) Section of the flexor synovialis from the carpal canal of a fifty-four-year-old woman with carpal tunnel syndrome, demonstrating mild nonspecific tenosynovitis. Note that the synovial membrane is slightly thickened and that the subsynovial tissue shows mild increase in fibrous tissue and a small amount of edema (hematoxylin and eosin; magnification x100 before reduction). (b) Section of the flexor synovialis of a fifty-year-old-woman demonstrating moderate nonspecific tenosynovitis. Note the thickened synovial layer, increased vascularity and moderate numbers of inflammatory cells in the subsynovial tissue (hematoxylin and eosin; magnification x95 before reduction). (c) A section of the flexor synovialis from a fifty-four-year-old woman demonstrating marked nonspecific tenosynovitis. Note the thickened synovial layer and increase in fibrous tissue and inflammatory infiltrate along the vessels and in the subsynovial layer (hematoxylin and eosin; magnification x75 before reduction).

Comment

The earliest symptoms are related to autonomic dysfunction and are poorly localized; they consist of vague sensations of discomfort in the hand. As the condition increases in severity, the patient complains of swelling, tightness, and redness of the hand. In the past these symptoms were referred to as "acroparesthesiae"; sometimes they extend into the forearm and occasionally into the upper part of the arm.

Paresthesias

The paresthesias are experienced first at night and later during the day. During the day most patients experience symptoms intermittently when using the hand. Symptoms seem to lessen during vacations with inactivity and rest and to worsen after a hard, long day of work or sometimes during cold weather.

When continuous hypesthesia or anesthesia occurs, patients become aware of impaired tactile discrimination in the fingers, and fine movements of the fingers are performed clumsily and with difficulty.

Atrophy and Weakness

With pain and weakness of the thenar muscle, a decrease in power of grip and an inability to grasp articles is manifested. Atrophy of the thenar muscles is a comparatively late finding in most cases and is accompanied by impaired opposition of the thumb. In far-advanced stages of carpal tunnel syndrome, atrophy of the thenar muscles produces a characteristic grooving of the thenar eminence (Fig. 11). Thenar wasting antedated dysthesia in fifteen patients in our group.

Vasomotor Disturbances

Vasomotor disturbances such as Raynaud's phenomenon, trophic ulcers and differential sweating in the palm and finger tips are encountered with carpal tunnel syndrome.

*Brachial Plexus Syndrome**

The thoracic outlet syndromes are not as common as was once thought. Many cases of carpal tunnel syndrome were at one time mistaken for thoracic outlet syndrome. Seven patients in our series had had scaleniotomy or cervical rib resection previously without relief of their original symptoms of paresthesias. It is now realized that obliteration of the radial pulse on Adson's maneuver does not necessarily indicate that paresthesias are due to a thoracic outlet syndrome. Roentgenograms showed evidence of asymptomatic cervical ribs in twenty-one of 697 of our patients.

---

*See page 34.

Compression of Median Nerve

Compression of the median nerve between the two heads of the pronator teres during its passage into the proximal forearm or at the site of a supracondylar process of the humerus rarely produces symptoms similar to those of carpal tunnel syndrome. The presence of fatty connective tissue in the carpal canal of obese patients, and the fact that the carpal canal is smaller in females than in males, may help to explain the predilection for compression of the median nerve in females. Tanzer stated that heredity and anatomic abnormalities are predisposing factors. Congenital anomalies such as an anomalous median artery, anomalous sublimis slip in the carpal canal and anomalous pathway of the motor branch of the median nerve through the transverse carpal ligament are rare causes of carpal tunnel syndrome. Many authors have shown that flexion and extension of the wrist result in increased pressure within the carpal canal.

Lower Motor Neuron Lesions

Occasionally, thenar atrophy is associated with lesions of the lower motor neuron such as anterior poliomyelitis or progressive muscular atrophy. In the former, the entire thenar group of muscles including both heads of the flexor pollicis brevis muscle is involved, and there is no sensory loss; in the latter, all the intrinsic muscles of the hand are generally involved.

Other conditions such as tumors of the spinal cord, syringomyelia, subacute combined degeneration, multiple sclerosis, degenerative disease of the spinal cord, amyotrophic lateral sclerosis, polyneuritis, local lesions involving the brachial plexus or cervical roots, aneurysm of the subclavian artery, and brain tumors can produce weakness and paresthesias of the hand. The diagnosis usually can be made after a detailed neurologic examination if one keeps in mind the anatomy of the involved extremity. Electromyography is the best aid for distinguishing most neurologic conditions from carpal tunnel syndrome.

Peripheral Vascular Disease

Some writers have considered ischemia to be important in the pathogenesis of the syndrome. We found a greater degree of peripheral vascular disease associated with the

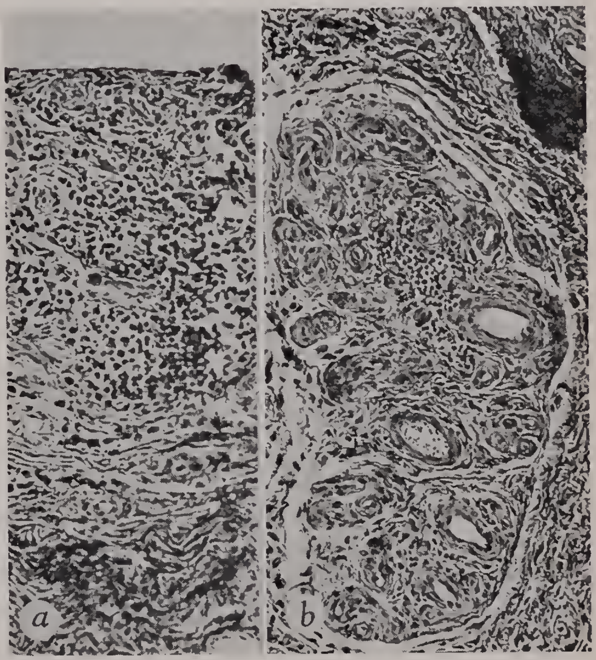

Fig. 9 — (a) Section from the flexor synovialis of a fifty-five-year-old man with severe marked nonspecific tenosynovitis. Note the greatly thickened synovial layer infiltrated with lymphocytes and plasma cells (hematoxylin and eosin; magnification x200 before reduction). (b) Section from the flexor synovialis of a thirty-eight-year-old woman with marked nonspecific tenosynovitis. Note the thickened synovial layer in the upper right hand corner. This section demonstrates the greatly increased vascularity simulating granulation tissue or hemangioma; there are moderate numbers of inflammatory cells around the blood vessels and some increase in fibrous tissue in the subsynovial tissue (hematoxylin and eosin; magnification x160 before reduction).

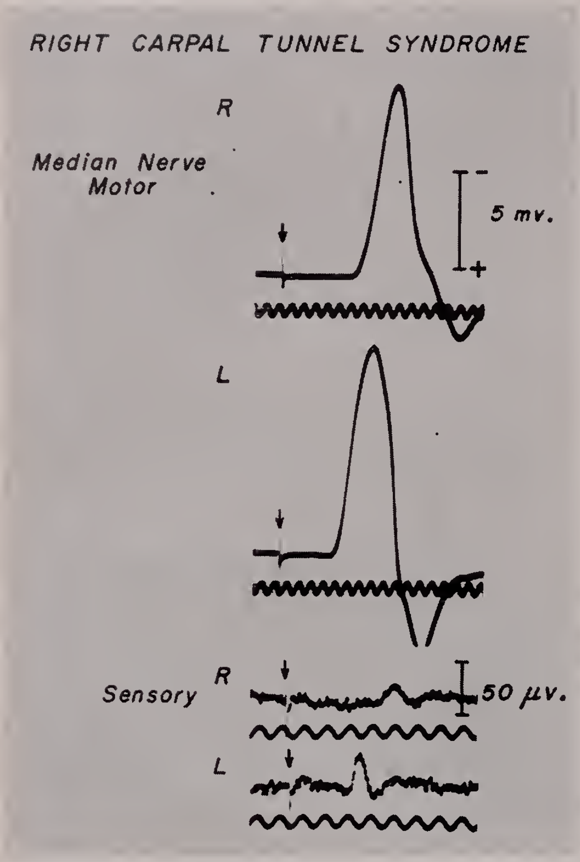

Fig. 10 — Electromyograms in the top two tracings show the action potential of the thenar muscles from stimulation of the median nerve at the wrist joint proximal to the carpal tunnel. The initial artifact (at the arrow) indicates the beginning of the electric stimulation. The gross wave shows the muscle potential. Each small wave represents one millisecond (1/1000 sec.).

In the right (R) hand the latency, from the artifact to the beginning of the action potential, is prolonged to 5.9 milliseconds (ms.). The left (L) hand has a latency of 4.3 ms. The upper limit of normal is 4.7 ms.

The first tracing of the right side shows a height of 5 millivolts on the top tracing and 50 microvolts on the bottom tracing. The bottom two electric tracings show the action potential of the sensory aspect of the median nerve from the tip of the index finger to the proximal part of the carpal tunnel at the wrist joint. The latency of response is 4.8 ms. on the right and 3.2 ms. on the left. The upper limit of normal is 3.5 ms. The velocity of nerve conduction from the elbow to the wrist joint was normal (R = 52 meter/sec.; L = 54 meter/sec.). (From Thomas, J. E., and Lambert, E. H.: Das Karpaltunnelsyndrom. München Med Wschr 104:123, 1962).

aging process and with diabetes (69 cases in our series). This finding was demonstrated in our microscopic examinations by an increased fibrosis around the small vessels in the subsynovial layer of the flexor synovialis and was noted in the control group and in most of the older patients having the carpal tunnel syndrome.

Physiologic Aging Process

From our study it was found that an aging process results in thickening of the flexor synovialis because of increased fibrosis and degenerative phenomena. It may be that occupational microtrauma enhances the aging process. As mentioned previously, 85 per cent of the patients with carpal tunnel syndrome in our series were more than forty years of age.

An association of the syndrome with certain "rheumatic conditions" was noted to occur in almost 20 per cent of the patients in our series (Table 4). It may be that in such patients the reaction of their connective tissue to trauma or other stimuli is altered. It has been postulated that estrogen deficiency plays a part in the production of nonspecific tenosynovitis and so-called rheumatic conditions. If such were the case, this might help to explain the preponderance of cases of carpal tunnel syndrome in women after menopause.

The group of 146 patients in our series with proved nonspecific tenosynovitis (sixty-five marked or moderate) adequately explains the production of symptoms on the basis of median-nerve compression in the carpal canal as a result of disproportion between contents and space. In sixty-two patients with only mild nonspecific tenosynovitis and in nineteen with normal flexor synovialis, a logical question is: Was the proliferation of the flexor synovialis in these patients sufficient to cause secondary compression of the nerve in the tight tunnel? In the control group as well as in 146 patients with proved nonspecific tenosynovitis, perhaps the degenerative process which produced thickening of the flexor synovialis contributed to compression of the median nerve, although it was normal for the older age group.

Summary and Conclusions

A clinicopathologic study was made of 1215 patients with carpal tunnel syndrome seen at the Mayo Clinic from 1930 to 1960. Of the 1215 patients, 756 were treated nonsurgically or were observed, and 459 were treated surgically.

The average age of the patients was 54 years; 85.3 per cent were more than forty years of age. The ratio of females to males was 2.25:1 and more than half of the patients were housewives. Bilateral carpal tunnel syndrome was present in 56.1 per cent of the patients, 26.1 per cent had involvement only on the right side, and 17.8 per cent involvement only on the left side. Patients had had symptoms for a few hours to forty years before they were seen at the Mayo Clinic.

The commonest clinical findings were paresthesias, thenar atrophy or thenar muscle weakness, positive results to Phalen's test, and positive Tinel's sign. Thickening of the flexor synovialis was noted grossly in almost every patient operated on for carpal tunnel syndrome. Microscopically, the flexor synovialis revealed varying degrees of nonspecific tenosynovitis in 71.8 per cent of the studied cases. Usually it was traced to a degenerative process that occurred with aging or systemic disease.

Early surgical decompression of the carpal tunnel by sectioning or resecting part of the transverse carpal ligament is highly successful in preventing progression of the symptoms and signs due to compression of the median nerve in the carpal canal. Permanent sensory and motor loss may follow prolonged compression of the median nerve in the carpal canal. Recurrence is rare after surgical decompression of the median nerve.

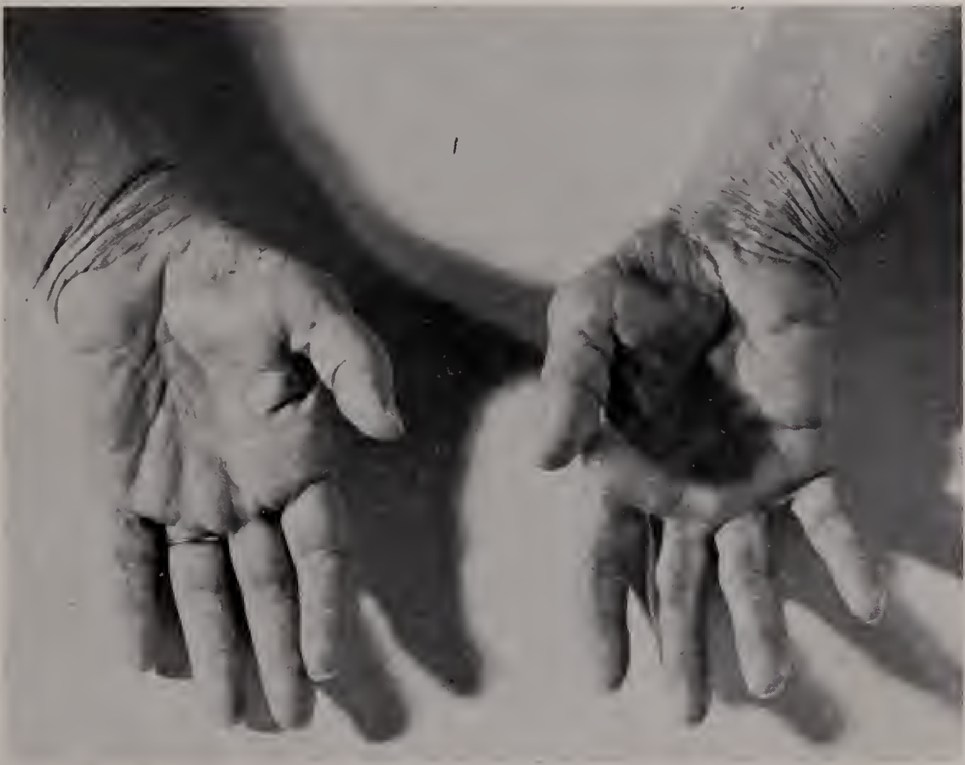

Fig. 11 — The hands of a patient having bilateral carpal tunnel syndrome with thenar atrophy. Note that the abductor pollicis brevis muscle is primarily involved but the flexor pollicis brevis is not greatly atrophied. The result is a shelflike appearance of the thenar eminence.

BRACHIAL PLEXUS SYNDROME

(Scalenius Anticus Syndrome) (Haven's Syndrome)

The brachial plexus syndrome results from the mechanical narrowing of the thoracic outlet space, causing pressure or torsion on the vessels and nerves supplying the upper extremities. There may be a considerable number of mechanical factors or anatomic deviations to cause this. The compression may be on the nerve, causing peripheral nerve disturbances with atrophy, pain, weakness, etc., or it may be on the artery, causing impaired circulation to the upper extremities.

Resection of the scalenius anticus tendon does not always provide benefit. It has been recommended by some authors that conservative and postural exercises be used before recommending surgical operation.

IT'S THE LAW

Physicians and Surgeons Prohibited from Splitting Fees

It shall be unlawful for any physician or surgeon to divide fees with, or to promise to pay a part of his fee to, or pay a commission to, any other physician or surgeon or person who calls him in consultation or sends patients to him for treatment or operation.

Punishment for Violation

Any physician or surgeon who pays or receives any money prohibited by section 147.11 shall be punished by a fine not to exceed $100.00, or by imprisonment in the county jail for not to exceed 90 days.

Revocation of License

In case a physician or surgeon shall be convicted of violating any of the provisions of section 147.11, the State Board of Medical Examiners, upon a first conviction, may, and, upon a second conviction, shall revoke the license of the person so convicted, but such revocation shall be subject to the right of the person whose license has been so revoked to appeal to the district court of the proper county on questions of law and fact.

Minnesota Statutes 147.11, 147.12, 147.13.

Captain Cook's Spruce Beer for Scurvy

At the turn of the century, Captain Cook provided his crew with sauerkraut, and encouraged them to seek wild vegetables whenever he landed to preserve their health during a four-year voyage in his ship Discovery. He also provided them with spruce beer, which was considered to be agreeable and wholesome, suggesting that this be drunk instead of rum, despite the fact that the sailors did not relish the change.

The beer was made as follows:

Boil down to concentration young black spruce fir branches — ½ pt.

Add bruised pimento — 4 ounces, ginger — 4 ounces, and water — 3 gallons.

Boil for 5 or 10 minutes, strain, and add 11 gallons of warm water, 1 pint of yeast, and 6 pints of molasses.

Mix and allow the mixture to ferment for 24 hours. Drink abundantly.

Comparative Incidence of Mycotic Diseases Involving the Adrenal Gland[‡]

MORTON I. BROOKLER, M.D.*
WILLIAM J. MARTIN, M.D.**
CLIFFORD F. GASTINEAU, M.D.**
ROBERT C. BAHN, M.D.†
Rochester, Minnesota

THIS STUDY was undertaken in an attempt to ascertain the incidence, type, and degree of involvement of the adrenal glands in patients who have various mycotic infections.

Materials and Methods

Sixty-two cases of systemic mycotic infections in which necropsy had been carried out at the Mayo Clinic during the period 1917 through October 1, 1960, form the basis of this report. The case records and necropsy protocols were reviewed. The gross adrenal specimens available were re-examined, and additional microscopic sections were made of them and stained. The histochemical stains employed included hematoxylin and eosin, azure eosin (pH 4.5), silver chromate, Gram, periodic acid-Schiff, and the acid-fast. The elastic van Gieson and Mallory-Heidenhain stains were applied later to delineate vascular involvement.

Criteria used to verify the diagnosis of a fungal infection included the results of antemortem and post-mortem cultures, when available, and histologic identification of the organism in the adrenal glands as well as in other organs.

Anatomic destruction of the adrenal cortex was graded on a 0 to 4 basis on examination of both gross specimens and microscopic sections. Grade 0 signified essentially intact adrenal glands; small, infrequently-occurring granulomatous foci of organisms were included in this grade. Grade 1 destruction was employed when at least 10 per cent of the adrenal tissue was intact, grade 2 when approximately 5 to 10 per cent remained intact, grade 3 when 5 per cent or less remained intact, and grade 4 when no intact adrenal cortical tissue could be demonstrated.

Results

The fatal granulomatous infections in the 62 cases are listed in the Table. The adrenal glands were involved by the mycotic process in 13 of the 62 patients (21 per cent). Of

TABLE
Distribution of Cases According to Mycotic Disease and Incidence of Adrenal Involvement

Mycotic disease	Number	Number with adrenal involvement	Incidence, per cent
Actinomycosis or nocardiosis	33	2	6
Cryptococcosis	9	3	33
Histoplasmosis	8	8	100
Aspergillosis	7	0	0
Blastomycosis	2	0	0
Coccidioidomycosis	2	0	0
Sporotrichosis	1	0	0
Total	62	13	21

these 13 patients, eight had histoplasmosis, three had cryptococcosis, and two had either actinomycosis or nocardiosis, but the specific genus of the last two was not determined by the cultures made.

There were no massive destructive lesions of the pituitary glands or gonads in any of the 13 cases.

Of the 13 patients who had involvement of the adrenals, 10 were males and three were females. Ages ranged from seven months to 77 years.

Whether clinical adrenal insufficiency was present in these 13 cases was difficult to determine for several reasons: (1) In some cases, adrenal involvement was not suspected ante mortem and hence diagnostic procedures for this condition were not employed. (2) In certain cases, biochemical criteria were not available at the time the patient underwent clinical examination, even if the diagnosis was suspected. (3) In cases in which more than the one disease was present, the symptoms were difficult to analyze in retrospect, and it was not easy to distinguish the symptoms that were attributable to the specific disease.

Cryptococcosis (Fig. 1)

The adrenal involvement apparently is a more or less terminal event in this disease. The duration of the disease was longer in our patients with adrenal involvement than in those without such involvement. In patients with adrenal involvement, the disease was disseminated, while patients without adrenal involvement had more localized disease. Although three of our nine patients with cryptococcosis had adrenal involvement of grade 1, none presented evidence of adrenal insufficiency. However, adrenal failure due to cryptococcosis has been reported in the literature.[1]

The association of cryptococcosis with other diseases, especially lymphoma and leukemia, has been emphasized in the literature.[2-5] Hodgkin's disease was associated in one of our three cases in which the adrenals were involved. In two of these three cases, no ante-mortem or post-mortem cultures were available. However, in these two, typical Cryptococcus neoformans could be demonstrated histopathologically both in the adrenal glands and in the brain. In the third, positive cultures were obtained both before and after death.

Actinomycosis and Nocardiosis

Fungi in the family of Actinomycetaceae are indistinguishable morphologically (Fig. 2) in tissue sections and can be differentiated only with certainty by cultural technics.

Although cases of actinomycosis or nocardiosis comprised the largest group in our series, the adrenal glands were involved in only two of them. Organisms consistent morphologically with either species of Actinomyces or Nocardia were seen in the adrenals

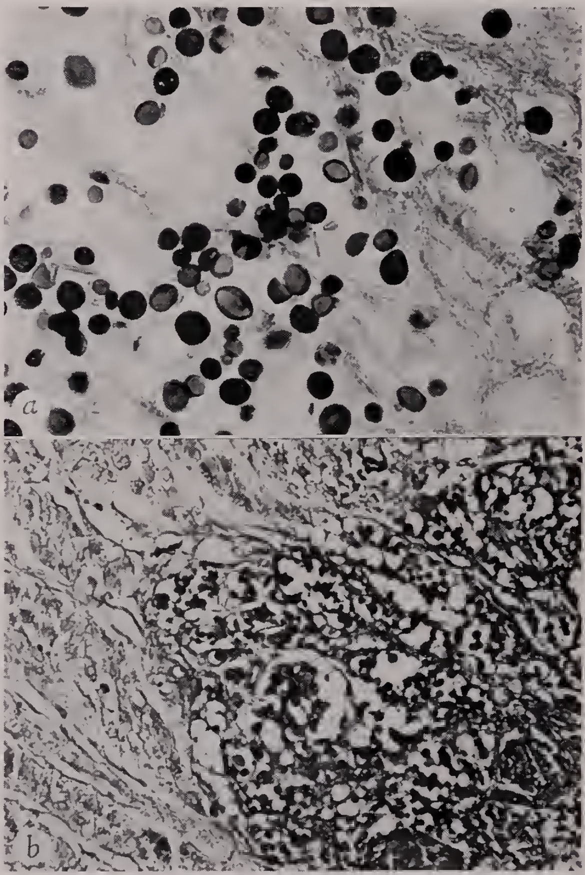

Fig. 1.*(a)* — Cryptococcus neoformans stains black in the center with silver chromate, whereas the capsule appears as a clear halo. Note budding in right upper corner of the field (silver chromate; x800). *(b)* Cortex of right adrenal gland of patient with disseminated cryptococcosis. The lesion is composed of yeastlike cells. A typical area is seen in right lower field. Grade of destruction is 0 (silver chromate; x200).

in both cases, and, in both, the adrenal involvement tended to be mild (grade 1) and unilateral. Direct extension was suggested by the finding of renal infection on the side affected; the opposite kidney was free of mycotic lesions. The disease in these two cases was more chronic than in the cases of either cryptococcosis or histoplasmosis in which the adrenal glands were involved. In one case, the process lasted two and a half years. The duration of the disease tended to be longer in the patients with adrenal involvement than in patients who had disseminated actinomycosis or nocardiosis. As was true of cryptococcosis, adrenal involvement seemed to be only a terminal event and a function of chronicity in these two cases. In both cases, there was no evidence of adrenal insufficiency. Although nocardiosis has been reported with adrenal involvement, as far as could be ascertained from the literature there has been no recorded case of actinomycosis that involved the adrenal glands.

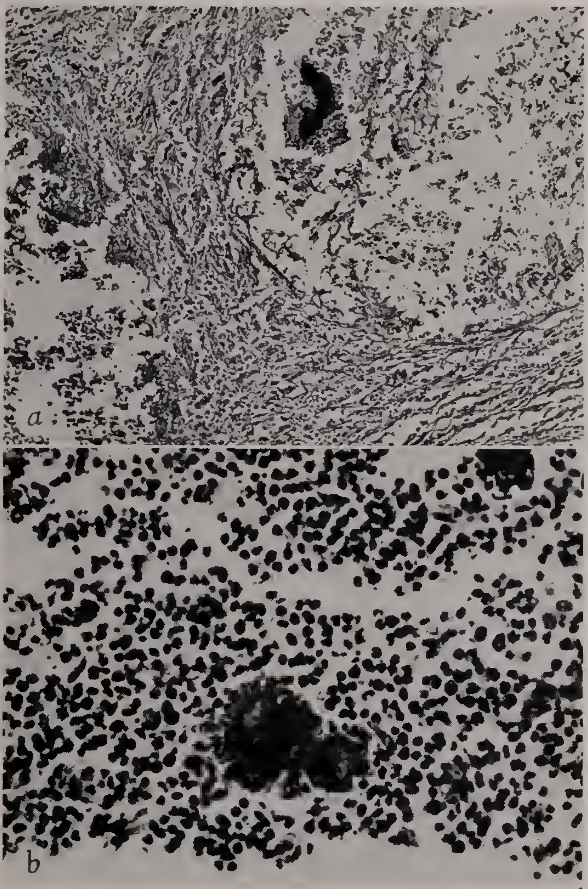

Fig. 2.(a) — Cortex of right gland of patient with findings compatible with actinomycosis or nocardiosis. The organism stains dark with silver chromate. Intact cortex is seen between the two abscesses. Grade 1 destruction (silver chromate; x100). *(b)* Cortex of left adrenal gland of same patient showing fungi. The central portion of ray fungus is gram positive. Grade 1 destruction (Gram; x400).

Histoplasmosis

Adrenal involvement was present in all eight cases of histoplasmosis; in four, destruction was graded 1 and in the remaining four, it was graded 3 or 4. The adrenal involvement was bilateral in five of the eight cases. The diagnosis was confirmed in all cases by both culture and identification of the organism in the adrenal gland, and the disease was disseminated throughout the body.

In four of the eight cases there was evidence of thrombosis in the central adrenal vein, which was bilateral in one case. This finding will be elaborated on in a separate report. Three of the four patients with suggestive evidence of clinical adrenal failure and the one patient with probable insufficiency demonstrated the vascular lesion.

Treatment

The patients who had cryptococcosis, actinomycosis, or nocardiosis were not treated with cortisone or allied agents. Four of the eight patients who had histoplasmosis with involvement of the adrenal glands had antemortem symptoms that suggested adrenal insufficiency, and one patient had probable insufficiency based on laboratory evidence. In these five cases, treatment with cortisone or allied agents was attempted, but the widespread disease and terminal status of the patient made recovery unlikely.

Comment

Our results with regard to cryptococcosis and nocardiosis or actinomycosis do not differ essentially from those of other investigators in regard to the incidence and the mildness of adrenal involvement and the rarity of Addison's disease due to such pathogens. Nocardia involves the adrenal glands only rarely and to our knowledge no reports that describe actinomycosis with such involvement have appeared in the literature.

The adrenal glands were involved in all eight of our cases of histoplasmosis; this was the highest incidence of adrenal involvement by a pathogen in our 62 cases. Review of the recent literature also indicates that histoplasmosis is the commonest mycotic process to involve these glands.[1,6]

Prior to 1934, only seven cases of histoplasmosis had been described in the literature.[7,8] One of the latest reviews of disseminated histoplasmosis was concerned with 25 cases. Nineteen of the 25 patients died; a necropsy study of 17 indicated that 14 had adrenal involvement.[9] The vascular changes found in adrenal glands involved by Histoplasma capsulatum may represent a hitherto unrecognized aspect of this disease. Sudden decline in the clinical status of a patient who has histoplasmosis may alert one to the possibility of hemorrhagic infarction of the adrenal gland.

Our findings corroborate the contentions that adrenal involvement is prominent in cases of generalized histoplasmosis, that such involvement is usually marked, and that the clinical picture of adrenal insufficiency is common.

The adrenal glands were not involved by the mycotic process in any of the cases with aspergillosis, coccidioidomycosis, blastomycosis, or sporotrichosis, but other investigators have described such involvement by Blastomyces dermatitidis and Coccidioides immitis. In one series of 347 cases of blastomycosis, adrenal involvement was present in two.[4,10] In another series of 90 cases of blastomycosis, the adrenals were involved in two.[11] Tuttle and Lichtwardt,[12] in 1953, reported a case of disseminated blastomycosis with adrenal involvement in which the organism simulated Histoplasma capsulatum. Forbus and Bestebreurtje,[13] in a review of 95 cases of disseminated coccidioidomycosis, found adrenal involvement in 16 cases; but in no case was there evidence of adrenal failure.

Summary

The adrenals were involved by the mycotic process in 13 of the 62 cases of mycotic infections that came to necropsy at this clinic from 1917 through October 1, 1960, giving a total incidence of approximately 21 per cent. The diagnosis in eight of these 13 cases was histoplasmosis, in three, cryptococcosis and in two, either actinomycosis or nocardiosis.

The adrenals were involved in all cases of histoplasmosis, and our results corroborate the contention that histoplasmosis is the fatal mycotic process that most consistently involves the adrenals. In five of the eight cases of histoplasmosis, death appeared to be secondary to adrenal insufficiency.

The adrenal glands were involved by the mycotic process in three of the nine cases of cryptococcosis, but symptoms were not suggestive of adrenal failure in any of these cases.

Thirty-three of the 62 patients had either actinomycosis or nocardiosis, but since only two had adrenal involvement without clinical findings suggestive of adrenal insufficiency, our results corroborate those in the literature that indicate the mild degree of adrenal involvement and the rarity of Addison's disease in these infections.

Of the 62 patients, seven had aspergillosis, two had blastomycosis, two had coccidioidomycosis, and one had sporotrichosis. None of the seven patients with aspergillosis had involvement of the adrenal glands by the mycotic process, although other investigators have described such involvement by blastomycosis and coccidioidomycosis.

Rice County Society Donates to Scholarship Fund

The Scholarship and Loan Fund of the Southern Minnesota Medical Association has now been in operation since 1958. Loans have been made to 25 students at the University of Minnesota Medical School. The loan fund has been made possible by donations from various medical societies in southern Minnesota and the Southern Minnesota Medical Association itself. Since its beginning the following medical societies have made donations: Wabasha Medical Society, Winona Medical Society, Blue Earth Valley Medical Society, Rice County Medical Society, Renville-Redwood County Medical Society, Steele County Medical Society, Zumbro Valley Medical Society, Blue Earth County Medical Society, Brown County Medical Society, and McCleod County Medical Society. This loan fund through the generosity of medical societies and doctors of southern Minnesota has grown to the sum of $11,614.10. Anticipating continued need for such funds has led the Rice County Medical Society to begin this year's contributions with a check for $500.

This Loan Fund is available to all students at the University of Minnesota Medical School without interest during their academic and internship periods. A small rate of interest is charged after the completion of their internship. One of the main purposes of this Loan Fund, in addition to helping the students, is to interest the students in going into the general practice of medicine particularly in the state of Minnesota.

There are people who fail because they are afraid to make a beginning; who go to bed tired because they spend the day looking for an easy job; who cannot tell what they think about anything until they see what the morning paper has to say about it.

Solid Cell Carcinoma

of
the
Thyroid

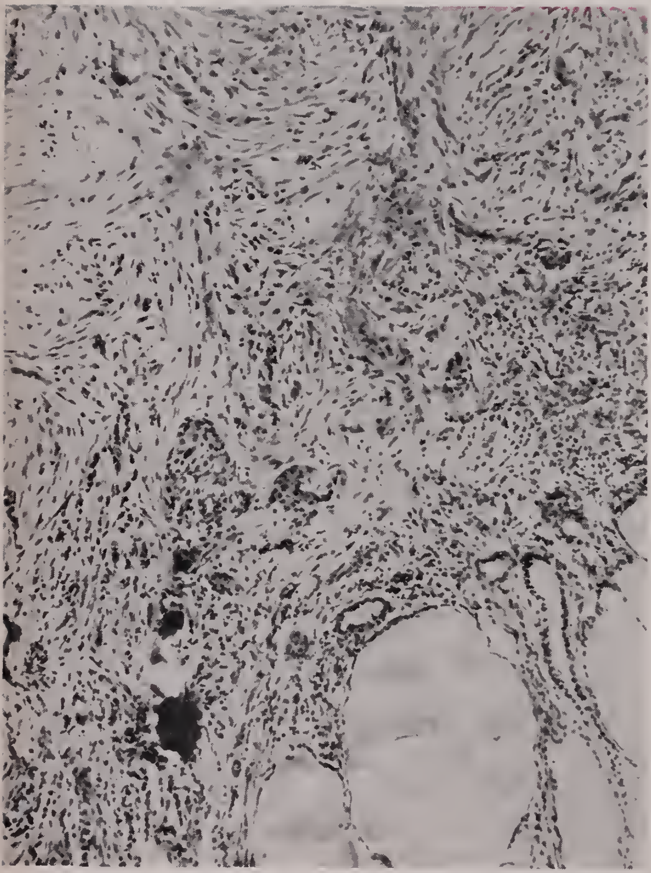

Fig. 1 — Solid Cell Carcinoma of Thyroid (H & E; x 250). Normal Acini Lower Right, Sheets of Tumor Cells with Fibrous "Amyloid" Stroma Above.

SOLID CELL carcinoma of the thyroid with amyloid stroma is an infrequently encountered malignancy of the thyroid gland, and its true significance has until recently been obscure. Our interest in this entity was stimulated by a patient who presented with just such a pathological picture.

Case Report

A 48-year-old male noted a mass in the right side of the neck in April, 1964. He consulted his local physician who removed a portion of the mass and submitted it for pathological examination. The microscopic appearance was felt to be characteristic of solid cell carcinoma of the thyroid with amyloid stroma. The patient was subsequently referred to this clinic for further evaluation and treatment. On examination the mass seemed to be lodged behind the sternoclavicular insertion of the right sternocleidomastoid muscle and fixed to the deep tissues. It appeared to be firm and rubbery. The thyroid gland proper was not enlarged. Multiple small nodes were palpable within the area of the anterior triangle of the right neck. The patient was clinically and chemically euthyroid and the tumor did not take up I^{131}. There was no evidence of direct invasion of the clavical or distant bone metastasis by X-ray examination.

At operation the entire thyroid gland had a normal appearance and consistency. A total right lobectomy, including the pyramidal lobe and isthmus, was car-

with Amyloid Stroma

ried out. The mass underlying the sternocleidomastoid muscle was removed in continuity with a radical right neck dissection. The cervical lymph nodes of the internal jugular chain up to the level of the jugular foramen were obviously involved with metastatic implants. The immediate postoperative course was complicated by diffuse bleeding from the operative area, requiring surgical control. Subsequently, however, the patient made an uncomplicated recovery and was discharged in early June of 1964.

Discussion

Medullary or solid carcinoma of the thyroid with amyloid stroma was first recognized as a distinct clinicopathologic entity by Hazard, Hawk and Crile[1] in 1959. As early as 1910, however, Stoffel[2] had noted the presence of unusual amyloid deposits in several specimens of thyroid carcinoma, and had speculated as to their origin and significance. Again, in 1951, Horn[3] presented seven cases of thyroid malignancy of an unusual type, some of which possessed many of the clinical and morphological characteristics of solid carcinoma. He did not, however, subject his material to stains for amyloid. It remained therefore for Hazard et al. to recognize and to focus attention on the true significance of this uncommon but important variant of thyroid carcinoma.

Solid Cell Carcinoma of Thyroid

Carcinomas of the solid cell type possess several distinctive morphological features. They are usually composed of moderate sized, round to oval shaped epithelial cells arranged in broad sheets, with little evidence of organization and with virtually complete absence of colloid production or papillary formation. This is in sharp contrast to other thyroid neoplasms, of which about 66% are mixed types. However, considerable variability in cellular morphology may be present; at times the tumor may closely resemble neurogenic sarcoma, transitional cell carcinoma, islet cell tumor of the pancreas or carcinoid.[1,4]

Interspersed among these clumps of cells are bands of connective tissue and an amorphous hyaline material which yields a yellow-green fluorescence when stained for amyloid. It is this material which provides the tumor with its most distinctive features. While some observers have noted periodic acid Schiff stain positive material in the normal juxtaneoplastic acini,[5] the amyloid is primarily intraneoplastic and intercellular in location. It is regularly found in the primary focus and in metastases as well. In addition, Russell et al.[4] have noted that the kidneys of seven of ten patients with solid cell carcinoma demonstrated tubular changes characteristic of plasma cell myeloma, and they infer from this that the tumor produces some as yet unidentified protein which is excreted via the kidney, exciting these tubular changes in transit. Vassar[5] has further elaborated on this hypothesis. He noted that Spicer[6] demonstrated an increased sialic acid component in thyroglobulin glycoprotein obtained from rats with experimentally induced thyroid carcinoma, and suggests that periodic acid Schiff stain positive material actually represents altered thyroglobulin produced by the tumor cells, indicating a certain degree of differentiation and functional activity. Further investigation on this subject is in progress.

Incidence

Review of the literature reveals 104 documented cases of solid carcinoma of the thyroid,[1,4,5,7,8,9] which appears to comprise from 3 to 10% of all thyroid malignancies. It is usually encountered in the sixth or seventh decade of life and is seen twice as frequently in women as in men. The presenting complaint is often goiter of long duration, frequently associated with enlarged cervical lymph nodes. One reported case[9] came to definitive surgery after a cervical node present for seven years proved to harbor solid cell carcinoma at biopsy. Woolner et al.[9] have documented four cases in which this tumor was probably present from 10 to 30 years at least. While there does not appear to be any favored location for the primary focus, a striking feature of this neoplasm is its tendency to spread to regional lymph nodes relatively early in the course of the disease. Hazard found 58% regional node involvement at the time of surgery, while Woolner noted 59.5% and Hirabayashi[8] 91%. Accordingly, a relatively high proportion of patients in this group undergo radical neck dissection. Distant metastases are not uncommon late in the disease, having a predilection for lung, liver and bone.[9]

Surgical Treatment

In general, the surgical treatment of solid carcinoma has been far from uniform, the majority of patients undergoing total or subtotal lobectomy. One of the most telling arguments in favor of utilizing radical subtotal or total thyroidectomy to treat the more common thyroid carcinomas is the fact that most appear to be multicentric in origin.[10-13] Russell et al. performed subserial sections on 80 glands removed for carcinoma and found that in 87.5% of them foci of tumor could be demonstrated in the isthmus or contralateral lobe. Most of this material, however, was of the papillary or mixed variety. Nevertheless, Woolner et al. found both lobes involved in 10% of their cases of solid carcinoma, while Hirabayashi noted a 41% incidence of bilaterality on routine serial sections. The actual number of glands containing solid carcinoma bilaterally may well be higher, since Russell found evidence of multicentricity in only 30% of his cases when sectioned in this routine manner.

Prognosis

Statistics indicate that solid carcinoma falls somewhat between the papillary and anaplastic varieties with regard to five-year survivorship. Woolner found a 75.6% five-year and 61.3% ten-year survival rate, which is in substantial agreement with other series. Hirabayashi compared solid carcinomas with follicular carcinoma of the invasive type and found a 20-year survivorship of 32.1% for the former, as opposed to 7.8% survivorship for the latter. The majority of deaths occurred from extensive local recurrences following surgery.

Summary

Solid carcinoma of the thyroid is a relatively uncommon neoplasm characterized by slow growth, early affinity for regional nodes, amyloid deposition in the tumor parenchyma, absence of "mixed" tumor elements, and long survivorship following adequate surgical extirpation.

Leo Rosten's Creed

We must forever oppose hysteria, even when it is wrapped in the vestment of patriotism.

We must learn that those we like are not always right, and those we don't like are not always wrong.

We must learn to seek change without violence.

We must try to understand each other by reconciling ourselves to the fact that most of us never really mature; we simply grow taller.

We must meet fanaticism with courage and idealism with a dose of caution.

We must be skeptical of that which is promised but not proved.

We must be strong enough to be gentle.

We must know that life will always contain unbearable stretches of loneliness.

We must have the great good courage to live without absolutes, without dogmas.

We must have the will to seek imaginative escape from conformity.

Vision

Don't worry too much about what lies ahead. Go as far as you can see, and when you get there, you can see farther on.—Great West Life Bulletin

Genius is the power of making continuous efforts.—Source unknown

Smoking Habits and Disease

E. CUYLER HAMMOND, Sc.D.
LEE BERGLUND, B.A.
RUTH KASLOW, B.S.
Minneapolis, Minnesota

A HIGH degree of relationship between cigarette smoking and death rates of men has been found in six previous prospective studies carried out in this country, Great Britain, and Canada.[1-6] In this paper, we will present findings on this subject in the first 35.5 months of follow-up in the Minnesota segment of a large prospective epidemiological study which was started in 1959 and is still in progress.[7-10]

Method of Study

During the latter part of 1959 and early 1960, volunteer workers of the Minnesota Division of the American Cancer Society enrolled 74,620 men and women, the mean date of enrollment being October 18, 1959. The study area encompasses 56 of the 87 counties of Minnesota. Upon enrollment, each subject answered a detailed questionnaire covering many factors including past and present smoking habits. The subjects are traced once a year and are requested to fill out brief questionnaires once every two years. In the most recent completed follow-up, 99.96% of the subjects were traced through September 30, 1962. (The next follow-up was started on October 1, 1963, and is still in progress.) When a death is reported, we request the Minnesota Health Department to supply us with a copy of the death certificate; and when cancer is mentioned on a death certificate we request the doctor to supply additional information.

This report is confined to the records of 31,733 men between the ages of 40 and 89 who were traced through September 30, 1962. Of these 31,733 men, 1,459 (4.6%) were reported to have died; and we now have copies of the death certificates on 1,455 of them. Cancer was mentioned on 262 of the certificates and doctors have provided additional information on 89% of them.

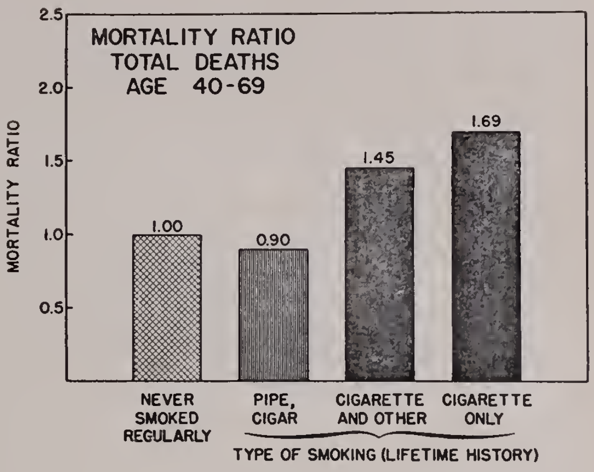
Physical Complaints

A list of various physical complaints was printed on the first questionnaire and the subject was asked to check "yes" or "no" after each of them to indicate whether or not he had the complaint "at present." Those who had a complaint were asked whether it was "slight," "moderate" or "severe." Of the 31,733 men between the ages of 40 and 89, 8,250 said that they were currently smoking 20 or more cigarettes a day and 8,403 said that they had never smoked regularly. Table 1 shows the number and percent of these smokers who reported having various complaints and the percent of non-

---

*Minnesota Division of the American Cancer Society and the Statistical Research Section of the Medical Affairs Department of the American Cancer Society, Inc.

in Minnesota*



smokers who reported having the complaints. The percentages for the nonsmokers have been adjusted to the age distribution of the cigarette smokers (this being necessary for comparability since the nonsmokers tended to be older than the cigarette smokers).

Pulmonary Symptoms

Cough, shortness of breath, and pain or discomfort in the chest were all reported far more frequently by the cigarette smokers than by the nonsmokers, the ratio being 2.98 to 1 for cough, 1.97 to 1 for shortness of breath and 1.38 to 1 for pain or discomfort in chest. Considering only subjects who reported these complaints to a moderate or severe degree, the ratios were 4.29 to 1 for cough, 2.52 to 1 for shortness of breath and 1.55 to 1 for pain or discomfort in chest. These findings are consistent with findings in histologic studies of changes in lung tissue in relation to cigarette smoking.[11,12] Such studies have shown a high degree of association between cigarette smoking and: (1) hyperplasia and the occurrence of cells with atypical nuclei in bronchial epithelium, (2) hyperactive glands in the walls of bronchial tubes, and (3) changes in the lung parenchyma including rupturing of alveolar septums, fibrosis and thickening of the walls of arterioles and small arteries.

Gastrointestinal Symptoms

Loss of appetite was reported over three times as frequently by cigarette smokers as by nonsmokers. One might expect this to be associated with loss of weight; and loss of weight during the preceding two years was reported somewhat more frequently by cigarette smokers than by nonsmokers. However, gain of weight was also reported somewhat more frequently by cigarette smokers than by nonsmokers. This suggests that fluctuations in weight may occur somewhat more frequently in cigarette smokers than in nonsmokers.

A number of other physical complaints such as hoarseness, nausea or vomiting, pain in stomach, indigestion, diarrhea and a tendency to "fatigue easily" were also reported somewhat more frequently by cigarette smokers than by nonsmokers. The picture in general indicates that cigarette smokers, as a group, tend to feel less physically fit than do nonsmokers.

Mortality

Table 2 shows the men classified by type of smoking (lifetime history). The figures under the heading "observed" are the actual number of deaths reported from the start of the study through September 30, 1962.

Nonsmokers

Figures under the heading "expected" are the number of deaths which would have occurred if the age-specific death rates in each group had been the same as the age-specific death rates of men who never smoked regularly. In other words, the age-specific death rate of the nonsmokers is taken as a standard for comparison. The mortality ratio is the observed number of deaths divided by the expected number of deaths. By definition, the mortality ratio of the nonsmokers is 1.00.

Cigarette Smokers

Men with a history of only cigarette smoking had by far the highest death rates (as indicated by their high mortality ratios). In age group 40 to 69, the death rate of such cigarette smokers was 69% higher than the death rate of nonsmokers; and in age group 70 to 89 the death rate of such cigarette smokers was 36% higher than the death rate of nonsmokers. (See Figure 1).

Cigarette, Pipe and Cigar Smokers

The death rate of men who smoked cigarettes and also smoked pipes or cigars (i.e., the "cigarette and other" group) was somewhat lower than the death rate of men who smoked cigarettes only. This is accounted for by the fact that men with mixed smoking habits tend to smoke fewer cigarettes per day and tend to inhale the smoke less deeply than do men who smoke only cigarettes.

Pipe and Cigar Smokers

The death rate of pipe and cigar smokers was close to the death rate of nonsmokers. This appears to be due to the fact that the great majority of pipe and cigar smokers do not inhale the smoke or inhale it only to a slight degree.

Table 3 shows further details on current cigarette smokers (i.e. men who were smoking cigarettes regularly at the time they enrolled in the study) with a history of only cigarette smoking. It is confined to men between the ages of 40 and 69 for the reason that there were relatively few such cigarette smokers among men in the older age groups. Some of the figures (particularly mortality ratios) are rather unstable statistically, due to small numbers. Figures for nonsmokers are included to give a basis for comparison.

Heavy Smokers

The mortality ratio increased substantially with the number of cigarettes smoked per day and was substantially higher among cigarette smokers who said that they inhaled the smoke deeply than among those who said that they did not inhale the smoke. The cigarette smokers who took up the habit before they reached their 20th birthday had higher death rates than did cigarette smokers who started the habit later in life.

Coronary Disease

Death certificates indicated that coronary artery disease accounted for 679 (46.5%) of the 1,459 deaths. Deaths from this cause were highly associated with the smoking habits of men in age group 40 to 69 but less highly associated with the smoking habits of men in age group 70 to 89. In age group 40 to 69, the coronary artery disease mortality ratios were: 1.00 for men who never smoked, 1.03 for pipe and cigar smokers, 1.75 for men who smoked cigarettes and also smoked pipes or cigars and 1.90 for men who smoked only cigarettes. The corresponding mortality ratios for men in age group 70 to 89 were 1.00, 0.98, 1.23 and 1.20 respectively.

Lung Cancer

Lung cancer accounted for 37 deaths (31 in age group 40 to 69 and 6 in age group 70 to 89). Four of these 37 men said that they had never smoked regularly and all of the others had a history of cigarette smoking.

Other Cancers

Previous studies have shown a relationship between smoking habits and the occurrence of cancer of the buccal cavity, pharynx, larynx, esophagus and bladder. Of 24 men who died of cancer of these sites, three said that they never smoked regularly, four were pipe and cigar smokers (who never smoked

TABLE 1

Physical complaints reported by 8,250 men who smoked 20 or more cigarettes per day and by 8,403 men who never smoked regularly. Age group 40 to 89.

Never Smoked Regularly	7,431	213	213.0	1.00

cigarettes), and 17 had a history of cigarette smoking.

Emphysema

Twenty men died of emphysema and all of them were smokers. Two smoked only pipes or cigars, seven smoked cigarettes and also smoked pipes or cigars and 11 smoked only cigarettes.

Hospitalization

At the time of the second follow-up (approximately two years after the start of the study) surviving subjects were requested to fill out a second questionnaire. On this questionnaire, they were asked whether or not they had been hospitalized since October 1, 1959 (the date the study was started). Of course, nonsurvivors did not fill out these questionnaires; but we assumed that all those who died had been hospitalized prior to death, this being true in the great majority of cases.

In Table 4, men aged 40 to 69 are classified in groups by their smoking habits as reported on the first questionnaire; and the percent hospitalized is shown for each of these groups. For comparability, the percentages have been standardized for age on the basis of the age distribution of all the men in the study.

TABLE 4

Percent of men hospitalized between start of study and second follow-up (approximately 2 years). Men aged 40 to 69 at start of study. Percentages are standardized for age on the total population of enrollees in the state.

Smoking Habits	Percent Hospitalized
Never Smoked Regularly	14.8
Cigar, Pipe	16.4
Cigarette and Other	20.2
Cigarette Only	19.6
Current Cigarette*	19.6
1-9 a day	16.0
10-19 a day	19.1
20-39 a day	20.1
40+ a day	24.7
Do Not Inhale	15.1
Inhale Slightly	18.5
Inhale Moderately	19.4
Inhale Deeply	23.9
Age Began Smoking:	
25 or older	15.9
20 to 24	18.2
15 to 19	20.7
Before age 15	23.7

*Men with a history of only cigarette smoking who were currently smoking cigarettes at the time of enrollment.

The general picture is much the same as that previously shown for total mortality. Only 14.8% of the men who never smoked were hospitalized within two years, while 19.6% of the men with a history of only cigarette smoking were hospitalized during the same period of time. Among current cigarette smokers, the risk of hospitalization increased with amount of smoking from 16.0% for those who smoked 1 to 9 cigarettes per day to 24.7% for those who smoked 40 or more cigarettes per day. The percent of men hospitalized was greater among cigarette smokers who said that they inhaled deeply than among those who said that they did not inhale; and it was greater among men who started to smoke cigarettes early in life than among those who started to smoke later in life.

Summary and Discussion

In this paper, we have reported on the smoking habits in relation to the physical complaints of 31,733 Minnesota men aged 40 to 89; and have reported the mortality and hospitalization experience of this group of men during the first 35.5 months after they were enrolled as subjects in a prospective epidemiological study. The findings are in good agreement with findings previously reported from other epidemiological studies on this subject.

Cigarette smokers report physical complaints (particularly cough, shortness of breath and loss of appetite) more frequently than nonsmokers, are hospitalized more frequently than nonsmokers, and have far higher death rates than nonsmokers. Among cigarette smokers, the frequency of physical complaints, the frequency of hospitalization and the death rate increase with amount of cigarette smoking, increase with degree of inhalation of the smoke and are higher among cigarette smokers who started to smoke early in life than among those who started to smoke late in life.

As in past studies, death rates from lung cancer, cancer of certain other sites, emphysema and coronary artery disease were found to be higher in cigarette smokers than in nonsmokers.

There is no need for us to review the literature and discuss other evidence on the subject of smoking and health since this has been done many times before. We conclude that cigarette smoking constitutes a major health hazard in Minnesota as well as in other parts of the world.

Acknowledgements

We would like to thank the 31,733 men who volunteered as subjects for this study; the volunteer workers of the Minnesota Division of the American Cancer Society who enrolled and traced the subjects; the Minnesota Department of Health that provided us with copies of death certificates; and the many physicians who provided us with additional medical information on subjects who died of cancer.

Hyperbaric Medical Facility*

CLAUDE R. HITCHCOCK, M.D.**
JOHN J. HAGLIN, M.D.**
FRANK E. JOHNSON, M.D.**
FREDERICK W. HOFFBAUER, M.D.†
Minneapolis, Minnesota

DURING RECENT months a complex hyperbaric research facility has been opened at the Hennepin County General Hospital. Designed as four chambers, this unit is the culmination of two and one-half years of engineering and construction. During the first six months of operation the chambers were used for 188 treatment cycles at a pressure of three atmospheres absolute (the pressure equal to 66 feet of depth in sea water). Many unique features of design and function have been incorporated in this unit and will be described.

Although attempts to apply conditions of high pressure environment to medicine have appeared sporadically over the years, not until our time has medical and surgical practice been well poised to pursue this method.[1] Early in our engineering of this facility we were impressed with the dangers inherent in the application of high pressures to human subjects. The need for maximum safety of both design and operation of hyperbaric chambers was paramount in our thoughts. In addition, the value of a unit containing multiple chambers permitting wide flexibility of operation on a clinical basis was appreciated. We believe our chambers are well suited to both basic and applied clinical research on a broad scale.[2]

Engineering, installation, and fitting out of the chambers were completed by the Vacudyne Corporation, Chicago Heights, Illinois. The Chicago Bridge and Iron Co., Chicago, Illinois, fabricated, erected and tested the steel vessels. The systems for high pressure reserve air and medical gases were engineered by the Air Products Corporation, Allentown, Pennsylvania; The Oxequip Co., Chicago, Illinois, designed, constructed and installed the control systems for medical gases, differential suction, and reserve air.

Historical Review

Robert Boyle, the English physicist, in 1659 was the first to show that a "vital material" in the air (oxygen) was necessary for maintaining life. His experiments demonstrated bubbles of gases which appeared in the tissues of animals if they died under conditions of decreased (hypobaric) ambient pressure. The first practical application of hyperbaric conditions, however, was made by Triger, a Frenchman, who in 1841 developed the first caisson for underwater construction work. In 1843 a Hungarian surgeon, Pravaz, first performed surgery under mild degrees of hyperpressure.[3]

---

*The hyperbaric research facility at the Minneapolis Medical Research Foundation, Inc. has been supported by two branches of the National Institutes of Health; Grant HE-07897-01 of the National Heart Institute, and Grant RC-1138 of the Division of Research Facilities and Resources. Matching construction funds have been provided by the F. A. Bean Foundation, Mr. John B. Hawley, Jr., General Mills, Inc., and the Baker Foundation, all of Minneapolis, Minnesota.

**Department of Surgery, Hennepin County General Hospital.
†Department of Medicine, Hennepin County General Hospital.

The problems of a possible improvement of anesthesia with hyperpressure were investigated by Fontaine in 1879 when he used an over-pressure of ⅓ to ¼ atmosphere in attempts to improve nitrous oxide anesthesia. Von Schrotter and associates in Austria in 1900 published the first scientific treatise on "caisson disease," or divers "bends," and decompression necessitated by the accumulation of inert gases in the body was established on a sound basis by Haldane about this same time.

The advent of high speed aircraft during recent years has again focused attention on medical problems incident to rapid ascent to higher altitudes. An early pioneer in this field was Henderson, who in 1917 wrote, "In order for bubbles to be formed it is essential . . . that the pressure with which tissues are in equilibrium should be lowered more than half its absolute amount in a few minutes. In the present state of the art of flying it is scarcely possible for an aviator to rise to a height of 20,000 feet where the barometer would be about half that of sea level in a period sufficiently brief to allow bubbles of nitrogen to form in this way. The disorders from which aviators suffer, therefore, are of a different class from those to which workers in compressed air are exposed."[4] It is immediately apparent that Henderson was aware of the possibility of decompression sickness through rapid ascent to high altitudes, but the aircraft of his day posed no serious problems to aviators. Now, however, in the space age, pilots are confronted with the same problem of decompression sickness as we jet them rapidly into the stratosphere, as is the diver in the sea or the personnel in a medical hyperbaric chamber as they emerge from a high pressure environment.

An early proposed medical application for hyperpressure was made in 1941 by Wangensteen and Lovelace when they considered the possible benefit of treating patients with bowel obstruction in a pressure vessel. Experimental studies with dogs were published in 1954 by Cross, but no significant clinical application was made of this method after that time.[5]

The present period of interest in hyperbaric phenomena was ushered in by Boerema and his colleagues in Amsterdam with their publications in 1956, 1959, and 1961.[6-8] A great impetus to this field of experimental work has been added by Illingworth and his colleagues writing from Glasgow of their experience in the treatment chamber at the Western Infirmary.[9] Specific applications of hyperbaric conditions to various disease states are now under investigation in several centers in the United States as well as in those already established in Europe.

Chamber Design

To accomplish flexibility of operation the Minneapolis hyperbaric unit contains three large chambers and one entrance lock. A central sphere, 19 feet in diameter, functions as a formal operating room and is connected on opposite sides to horizontal chambers which are nine feet in diameter and 18 feet in length (Figure 1) (Also cover). One horizontal chamber is separated from the operating sphere by the entrance lock, and this chamber and lock are designed for operation at seven atmospheres absolute pressure. The spherical operating room and the opposite horizontal chamber are constructed for a maximum operating pressure of four atmospheres absolute. With double doors between all chambers as they are connected in series it is possible to use any one chamber independently of the others or to use them in any combination desired at any given time.

The chambers are constructed of welded steel plate, and the entrance doors are rectangular in shape with a height of six feet and a width of 30 inches. Movement of patients and equipment between the chambers is facilitated by pneumatic floor ramps before each door to adjust for the differential elevations at the bulkheads (Figure 2). A medical "pass-through" lock is provided for each chamber, which is large enough to accommodate standard surgical packs and small-sized gas cylinders (Figure 1). The two chambers designed for operation at seven atmospheres absolute pressure were hydro-

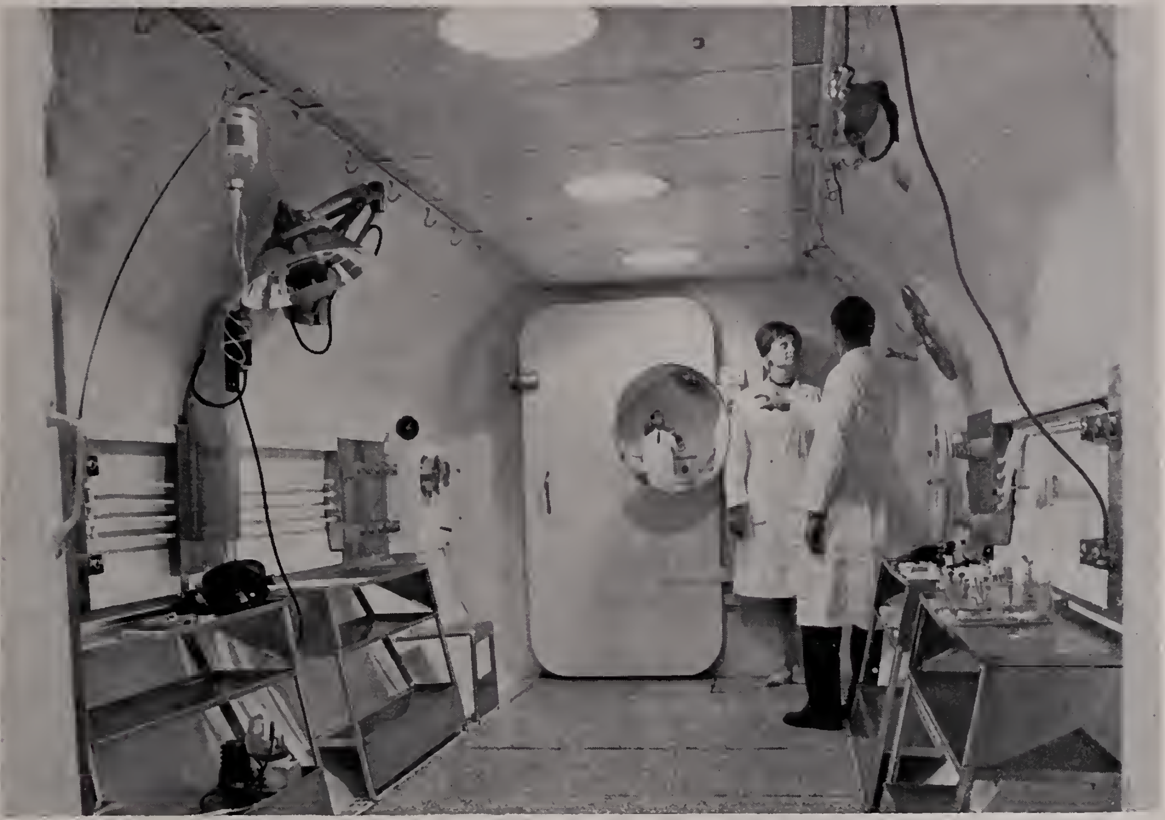

Fig. 2

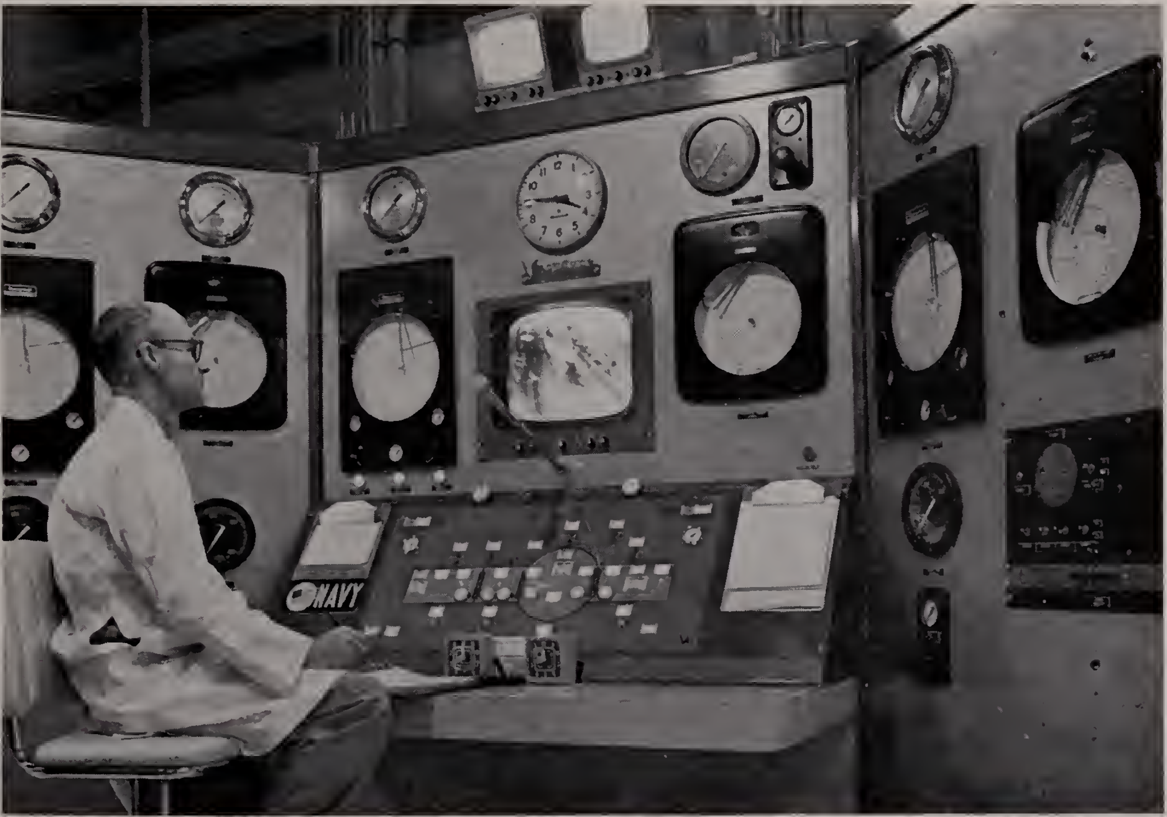

Fig. 3

statically tested with an inside pressure of 10 atmospheres (gauge), and the chambers designed for a maximum operating pressure of four atmospheres were tested with six atmospheres (gauge) inside pressure.

Methods for Pressurizing the Chambers

During ordinary operation the chambers are pressurized with outside air by one of two compressors of the horizontal reciprocating piston type and containing Teflon rings. The output of these compressors is rated at 198, and 160 standard cubic feet per minute. The air inlet is situated 50 feet above the ground (removed from carbon monoxide contamination) and contains filters to remove any particulate matter. The heat of compression is removed from the compressed air as it passes to the chambers through a system of pre-coolers, and final temperature control is effected within each chamber by a built-in air conditioning unit. Chilled brine circulates within these air conditioners and is supplied from a refrigeration unit in the mechanical room. Using one compressor for a given cycle of pressurization, either horizontal treatment chamber can be pressurized to three atmospheres absolute within eight minutes. More rapid pressurization is possible by using both compressors simultaneously.

Adequate ventilation of hyperbaric medical chambers is important for the safety of personnel involved. The Minneapolis unit can be ventilated, with all four chambers at three atmospheres absolute pressure, with a total of 600 standard cubic feet of air per minute. This will permit 20 standard cubic feet of air per minute for the ventilation of each of 10 persons within each of the three major chambers at any one time. Air enters the chambers at the top through inconspicuous grills and discharges at the bottom along the edges of the floor. There is no discomfort or noticeable flow of air during operation of any of the units.

For protection during an electrical power failure or mechanical failure of the compressors, a large volume of air (26,000 cubic feet) is stored in steel cylinders at 3000 pounds per square inch pressure. This high pressure "stored" air is connected for automatic discharge into the pressure system of the chambers in the event of operational failure, and will service one chamber for 12 hours. Anticipating the necessity of treating patients with the "bends" the entrance lock can be pressurized to seven atmospheres absolute within two to three minutes by using both air compressors simultaneously, or mechanically drawing air from the high pressure "stored" source. During chamber operation the flow of pressurized air to the chambers, once established by the operator, is automatically maintained by mechanical modulating valves. Pressure, temperature, and humidity of the air are constantly recorded on separate potentiometers for each chamber during all phases of operation.

Control System

Controls for the Minneapolis facility are semiautomatic and of a combined pneumatic and electrical type. Complete control during chamber operation is centered outside the chambers at a central control panel (Figure 3) and chamber operation is constantly monitored through a closed circuit television system. It is not necessary for the chamber operator to leave his station at any time. In addition to the visual contact through television the console operator is in constant communication with the personnel in each chamber through an intercommunication system. The control console for medical gases (not shown) is immediately to the front of the master control panel and is under constant surveillance by the chamber operator.

Safety Features

Anticipating the possibility of electric power failure, an auxiliary generating unit automatically provides 5000 watts of alternating current to activate the control systems and lights of the hyperbaric chambers and surrounding building. With the already described high pressure air system for chamber operation during emergency conditions, a total power failure can be accepted for many hours without interfering with work in progress within the chambers.

A high-pressure sprinkler system installed in each chamber can be activated either from inside the chamber or from an outside source. This provides a spray of water to all areas of the chamber in the event of fire or explosion. A complete set of auxiliary manual controls for chamber operation has been installed on the wall between the compressor room and the chamber room. The basic protocol for chamber operation calls for two operators at all times, and the manual controls can be manipulated during an emergency by one operator who remains in contact with his colleague at the central control panel through a separate telephone into the intercom.

Each medical pass-through lock (Figure 1) is equipped with a separate telephone connected to the loudspeaker system within the chamber serviced by that lock. Constant communication during a pass-through procedure minimizes any danger of malfunction.

Special Features

Hot and cold running water has been provided in each major chamber. A pressure of 120 lbs. per square inch maintained on this water supply at all times assures entrance of the water into the chamber irrespective of internal pressures involved. Discharge of waste material is accomplished to the sewer by means of special valves which open upon contact with liquid and close upon contact with air.

The use of closed circuit television viewing of each chamber has permitted an admirable arrangement for teaching classes in hyperbaric medicine. The Navy personnel who operate the hyperbaric unit now teach weekly sessions in the conference room for the orientation of nurses, technicians, and medical students.

Medical Gases

All medical gases piped to the chambers are stored in a separate building along with the high pressure "stored" air. The medical gases provided to the chambers consist of the following: oxygen, nitrogen, helium, special mixture No. 1 (helium 40% — oxygen 60%), special mixture No. 2 (nitrogen 40% — oxygen 60%), and nitrous oxide. These medical gases are reduced in pressure at the central gas control panel (not shown) and enter the chambers at a pressure, maintained by a system of differential control regulators, of 50 lbs. per square inch over the internal pressure within the chamber at any given time. Plug-in outlets within each chamber (as seen in Figure 2) permit demand regulator valves to be used with tight fitting masks for gas supply to the patients and technical personnel. A differential vacuum system in the gas control panel also provides a constant level of differential negative pressure for surgical suction. Alarm signals and lights are located on the gas control panel to warn of decreases in pressure within the tubes or faulty operation of the system.

Basic Physical Gas Laws Underlying Hyperbaric Physiology

The potential benefit of hyperbaric therapy depends upon an increase of physically dissolved oxygen in tissues. The physical gas laws, therefore, form the basis upon which this method of therapy is predicated. Henry's Law (1803) states the relationship of pressure to the solubility of gases, showing that the quantity of a gas dissolved into a liquid increases directly as the pressure exerted on the liquid by the given gas. The law governing a mixture of gases was formulated by Dalton (1807) and states that the quantity of a specific gas dissolved by a liquid depends upon the partial pressure of that particular gas in equilibrium with the liquid. Boyle's Law explains the relationship of gas volume to pressure, stating that, if temperature is constant, the gas volume is inversely proportional to pressure exerted on the gas.

The effects of pressure on the animal or human body must be interpreted in terms of tissues containing mostly liquid, and cavities containing air or gases. Recognizing that liquids are virtually incompressible we realize that the partial pressure of water vapor in the alveolar spaces of the lung is a function of temperature only and is nearly independent of ambient barometric pressure. Thus, it is immediately apparent that a complex organism under pressure in a hyperbaric chamber experiences a build-up of the gases breathed into the lungs in direct relationship to the pressure involved in the chamber itself.

At three atmospheres absolute pressure a subject breathing 100% oxygen from a tightly fitting mask will equilibrate after 12-15 minutes to have a partial pressure of oxygen in the femoral artery blood of approximately 2160 mm.Hg. It is this tremendous increase in partial pressure of oxygen available to the blood of the pulmonary capillaries which provides the physiological basis for the possible benefits of tissue "saturation" with oxygen. Under these conditions, all tissues of the body perfused from an intact circulatory system are saturated with physically dissolved oxygen from the plasma and interstitial fluid, and hemoglobin is not required for oxygen transport. The movement of carbon dioxide to the lungs for exhalation, however, does depend on the hemoglobin oxyhemoglobin system for optimum function, even under three or four atmospheres absolute pressure.

It is axiomatic, however, that tissues must be perfused in order to participate in a "saturation" process. Also, serious right to left shunts within the heart and lungs seriously reduce the possible build-up of physically dissolved oxygen in the circulating blood. However, in infants cyanotic from tetralogy of Fallot, pulmonary atresia, or transposition of the great vessels, treatment with 100% oxygen under three or four atmospheres absolute pressure accomplishes a more normal degree of oxygenation of the red cell mass and an improvement of the general condition for a period of time, permitting corrective or ameliorating surgery to be more safely performed.

Study of a normal dog breathing 100% oxygen under three atmospheres pressure reveals an alveolar Po_2 of 2172 mm.Hg (137 mm.Hg partial pressure in room air), an arterial Po_2 of 1975 mm.Hg (63 mm.Hg partial pressure in room air), a venous Po_2 of 89 mm.Hg (25 mm.Hg partial pressure in room air), and a Po_2 in the thoracic duct lymph of 588 mm.Hg (45 mm.Hg partial pressure in room air).[10]

Discussion

Large increases of oxygen in the animal or human body are not without attendant dangers. Oxygen toxicity has been recognized for many years and is still an unsolved problem. Current evidence indicates the likelihood that the central nervous system is the probable seat of the disturbing effects of muscular twitchings and convulsions. Normal human subjects breathing 100% oxygen at four atmospheres absolute pressure can rarely exceed 30-45 minutes without significant danger of convulsions. At three atmospheres absolute pressure the safe time for most normal subjects is extended to approximately three hours. At two atmospheres absolute pressure (one atmosphere over-pressure) subjects will tolerate the increased oxygen concentration for as long as 48 hours.

There is an inverse relationship between the time factor and the oxygen concentration to which the lungs are exposed. The partial pressure of oxygen in the blood and tissues is the critical factor. Thus, 100% oxygen at lower pressures would have the same effect as lower concentrations of oxygen at higher pressures for a given period of time. High oxygen concentrations for prolonged periods of time also have a deleterious effect on the lungs and the mucosa of the tracheobronchial tree. Considerable controversy still exists over these basic phenomena and further research studies will be necessary for more detailed delineation of the pathophysiology involved.

The Minneapolis hyperbaric research team is now engaged in a basic and clinical research program on a 24-hour basis. During the first six months of operation six patients have been treated for gas gangrene. Surgical debridement of the muscle involved with clostridium Welchii infection, plus hyperbaric oxygen at three atmospheres absolute pressure, and penicillin therapy have proved effective in bringing these infections under control. Best results will be achieved, however, if such patients can be treated immediately, once the diagnosis has been established. The clinical picture of clostridial myositis with toxemia, leukocytsosis, and high fever should be taken as an indication for therapy with hyperbaric oxygen. Four of our six patients have recovered uneventfully and one who expired was in a state of extremis upon arrival at the hospital; although improvement was noted following the first three-hour treatment in the chamber, the patient expired with a high potassium level (over 9 mg.%) due to excessive red cell destruction by the circulating toxins.

Since in vitro studies indicate that other infections may benefit from hyperbaric oxygen therapy, it is important that clinical investigation be more thoroughly pursued. The problem of tuberculosis also needs research emphasis as the months go by.[11]

Infants with seriously crippling heart disease such as those with tetralogy of Fallot, pulmonary atresia, transposition of the great vessels and tricuspid atresia can be quickly improved when treated with hyperbaric oxygen; surgery can be performed more safely under these improved conditions.

Other Areas of Likely Research in Hyperbaric Medicine

Other areas of likely research are as follows:

1. Acute respiratory insufficiency (for example the patient with traumatic wet lung and serious pulmonary edema, or the patient suffering from bilateral chemical pneumonia or aspiration pneumonia).
2. Patients with ischemia problems such as myocardial infarction, cerebral vascular occlusion, mesenteric artery occlusion, and vascular injuries in the extremities.
3. Patients with hypovolemic or septic shock.
4. Patients with carbon monoxide poisoning.
5. Cancer; a program of research is underway testing the possible abetment of the action of anticancer agents with hyperbaric oxygenation.
6. Organ grafting. The Minneapolis chambers are now used for harvesting kidneys from human cadavers. Immediately upon death a cadaver placed within the chamber under three atmospheres pressure is perfused with a pump oxygenator using the femoral artery in one leg and both femoral veins. With cross-clamping of the aorta at the level of the diaphragm the kidneys are perfused with blood carrying a Po_2 of 2000 mm.Hg or more partial pressure of oxygen. It is possible, under these conditions, to harvest organs after many hours of ischemia time (three or more) with an improved function upon vascularization within the recipient.

Preliminary studies in the laboratories of our research foundation have indicated a 43% improvement in the healing of experimental wounds in dogs when the animals are treated with hyperbaric oxygenation for the first four days post incision. This area of work needs to be expanded and to also include the potential of hyperbaric oxygen in the healing of fractures.[12,13]

Caution must be the byword for those working in the field of hyperbaric medicine. Ordinarily, the patient is the only person to be considered regarding safety and morbidity inherent in a given method or procedure. However, in the case of hyperbaric oxygenation, either as therapy or as an adjunct to surgery, far greater problems are encountered. Everyone involved, including the medical and paramedical personnel as well as all individuals and property in the surrounding area, can be jeopardized with an improperly constructed or operated hyperbaric facility. It is incumbent upon all who enter this field to do so forearmed with as much basic knowledge of the problems involved as possible. We are pleased to provide the hyperbaric research facility at the Hennepin County General Hospital to the communities of the Central Northwest for the advancement of medical and surgical knowledge.

One of the Surgical Operations on President Cleveland in 1893

(As Narrated by W. W. Keen)

Doctor Hasbrouck first extracted the two left upper biscuspid teeth (very badly ulcerated) under nitrous oxide. Doctor Bryant then made the necessary incisions in the roof of the mouth, also under nitrous oxide.

At one-fourteen P.M. ether was given by Doctor O'Reilly. During the entire operation Doctor Janeway kept close watch upon the pulse and general condition. Doctor Bryant performed the operation, assisted by myself and Doctor Erdmann.

The entire left upper jaw was removed from the first bicuspid tooth to just beyond the last molar, and nearly up to the middle line. The floor of the orbit — the cavity containing the eyeball — was not removed, as it had not been attacked. A small portion of the soft palate was removed. This extensive operation was decided upon because we found that the antrum — the large hollow cavity in the upper jaw — was partly filled by a gelatinous mass, evidently a sarcoma. This diagnosis was later confirmed by Dr. William H. Welch, of the Johns Hopkins Hospital, who had also examined the former specimens.

The entire operation was done within the mouth, without any external incision, by means of a cheek retractor, the most useful instrument I have ever seen for such an operation, which I had brought back with me from Paris in 1866. The retention of the floor of the orbit prevented any displacement of the eyeball. This normal appearance of the eye, the normal voice, and especially the absence of any external scar, greatly aided in keeping the operation an entire secret.

Only one blood vessel was tied. Pressure, hot water, and at one point the galvanocautery, checked the bleeding. The hemorrhage was not large, probably about six ounces — say, a tumblerful — in all. At the close of the operation, at one-fifty P.M., the pulse was only eighty. The large cavity was packed with gauze to arrest the subsequent moderate oozing of blood. At two-fifty-five P.M. a hypodermic of one-sixth of a grain of morphine was given — the only narcotic administered at any time.

What a sigh of intense relief we surgeons breathed when the patient was once more safe in bed can hardly be imagined!*

LOMOTIL®

Each tablet and each 5 cc. of liquid contains:

diphenoxylate hydrochloride	2.5 mg.
(Warning: May be habit forming)	
atropine sulfate	0.025 mg.

- lowers motility promptly
- relieves spasm promptly
- stops diarrhea promptly

Lomotil fulfills the first order of treatment in most patients with diarrhea – prompt symptomatic control.

Pending discovery of the cause, early cessation of diarrhea is almost always urgently indicated. Prompt symptomatic control averts distress, dehydration and, frequently, severe exhaustion.

Both experimental and clinical evidence indicates that Lomotil exerts such control efficiently, safely and with maximal promptness.

dosage:

The recommended initial *adult* dosage is two tablets (2.5 mg. each) three or four times daily, reduced to meet the requirements of each patient as soon as the diarrhea is controlled. Maintenance dosage may be as low as two tablets daily. *Children's* daily dosage (in divided doses) varies from 3 mg. for a child of 3 to 6 months, to 10 mg. for one 8 to 12 years of age.

cautions and side effects:

Lomotil is an exempt narcotic; its abuse liability is low and comparable to that of codeine. Recommended dosages should not be exceeded. Side effects are relatively uncommon but among those reported are gastrointestinal irritation, sedation, dizziness, cutaneous manifestations, restlessness and insomnia. Lomotil should be used with caution in patients with impaired liver function and in patients taking addicting drugs or barbiturates.

Lomotil is a brand of diphenoxylate hydrochloride with atropine sulfate; the subtherapeutic amount of atropine is added to discourage deliberate overdosage.

President's Letter

From the time of his election in May until he assumes the duties of his office on the first day of January, the president-elect of the Minnesota State Medical Association has time to reflect on his responsibilities. He usually has had years of experience in committee or council activity and has observed the work of previous presidents. I have had the good fortune to serve for several years in the council where the accomplishments of dedicated and able presidents have inspired me. Upon their experience and sound advice I shall rely heavily. Although the president sits with council, he does not vote. He is not primarily involved in policy decisions, which are the province of the House of Delegates and are carried out by the council.

As I have interpreted the duties of the president, he has three primary areas of responsibility. He serves as the chairman of the scientific program committee. This means that he must begin planning for the May meeting before he assumes office. I hope that the coming program will prove stimulating enough to attract all of our members to the meeting in Minneapolis in May, 1965. The president also must appoint certain committees that will function during the year of his tenure. This is an important task and will be the subject of a subsequent letter. Perhaps the most difficult of the president's duties is to represent the Association as he listens to the deliberation of the House of Delegates and the council and serves as spokesman both to the Association and for the Association in professional and public relationships. It is obvious that to discharge these duties adequately, the president must be informed and he should be accessible to all who have a legitimate call for his ear or his voice.

One of my first interests as your president-elect was to review the components of the State Medical Association. Who are the physicians who make up this organization? In September, 1964, there were 3893 members from a total of 4993 licensed physicians in Minnesota. The directory of the American Medical Association indicates that approximately 45 per cent are in specialty practice and 55 per cent in general practice. There are more than 150 groups of three or more physicians; about 20 per cent of these groups involve a single specialty. As physicians from a state with outstanding schools of undergraduate and graduate medical education, we have an increasing number of faculty and students who are regular or residency members. The physicians who staff our state and federal medical institutions are a relatively small but significant portion of the

MILTRATE®

meprobamate 200 mg. + pentaerythritol tetranitrate 10 mg.

Effective tranquilization
plus
long-acting coronary vasodilation
for
prophylaxis of pain in angina pectoris

Indications: 'Miltrate' is useful for prophylaxis of pain in angina pectoris and coronary insufficiency, especially where anxiety is a factor. **Contraindications:** Like all nitrates, pentaerythritol tetranitrate should be avoided or prescribed cautiously for patients with glaucoma. Previous allergic or idiosyncratic reactions to meprobamate contraindicate subsequent use. **Precautions:** *Meprobamate* —Patients engaged in activities requiring alertness should be warned of drowsiness. Meprobamate may increase the effects of excessive alcohol, and the possibility of dependence should be considered, particularly in patients with a history of drug or alcohol addiction. Sudden withdrawal may result in reactions, rarely epileptiform seizures. Grand mal attacks may be precipitated in persons susceptible to both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies. **Side effects:** *Pentaerythritol tetranitrate*—The most common side effects are transient headache, nausea, and rash. Weakness, palpitation, flushing, gastrointestinal distress, and lightheadedness have been reported on a few occasions. *Meprobamate* —May cause drowsiness and, rarely, ataxia, usually controlled by decreasing the dosage. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses of the drug. Mild reactions include urticarial or maculopapular rash. Serious reactions, rarely encountered, include dermatological effects, acute nonthrombocytopenic purpura, chills, fever, fainting spells, angioneurotic edema, bronchial spasm, hypotensive crisis, anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic, and the drug not be reinstituted. **Dosage:** Usual dosage is one or two tablets before meals and at bedtime. Individualization of dosage is required for maximum therapeutic effect. Doses above twelve tablets daily are not recommended. **Supplied:** White tablets, each containing meprobamate 200 mg. and pentaerythritol tetranitrate 10 mg. *Before prescribing, consult package circular.*

The Gold Headed Cane Tradition

FIVE RETIRING medical staff members from the Mount Sinai Hospital were given distinctive canes at an honorary dinner upon retirement from the active staff: Drs. Moses Barron, Samuel Dworsky, Charles Hymes, Virgil Schwartz, and Max Seham. In the presentation of the canes, the history of the London gold-headed cane was reviewed:

"From the time of antiquity the staff, rod or cane has been associated with the lore and art of medicine. Our modern symbol of medicine, the caduceus, bears the winged staff of Mercury, the intermediary between man and the Gods, around which is wrapped a serpent to portray the renewal of life after illness or shedding of the skin. Probably the most famous biblical reference to this association of medicine is the shepherd's staff from the 23rd Psalm. 'Thy rod and thy staff they comfort me.' The physician is in many a sense the shepherd whose staff restoreth both body and soul.

"In more modern times the famous Gold-Headed Cane of London became the hallmark and mace of leadership in Medical Practice. In 1825 it was presented to the Royal College of Physicians by the widow of Mathew Baillie, the last of the five wearers of the cane. There it remains today, a symbol of an era of excellence in the art and practice of Medicine.

"The first owner of this elegant walking stick was Dr. John Radcliffe who in 1669 was physician to Queen Anne and King William III. Radcliffe's heir apparent and next recipient of the Cane was Richard Mead, who amongst his other accomplishments experimented with small pox vaccination 25 years before Jenner. The third owner of the Cane was Anthony Askew, about whose medical accomplishments little is known. Not much more is known of the fourth custodian of the Cane, Dr. Archibald Pitcairn, other than that his brother, Major Pitcairn was killed at the battle of Bunker Hill. The fifth and last to accept the Cane as the mantle of leadership in medical practice of London was Mathew Baillie, well known anatomist and physician, and nephew of John and William Hunter.

"You gentlemen have brought to our staff strong, diverse, highly individual personalities. Your retirement from active practice will leave a void of personal devotion, individual excellence, and highly developed skills that our generation will find difficult to replace.

"With great pleasure I present to each of you from your many friends and colleagues, this silver-headed walking stick in appreciation of your long, devoted and distinguished service to the best of medicine and medical practice."

Arnold J. Kremen, M.D.
Minneapolis, Minnesota

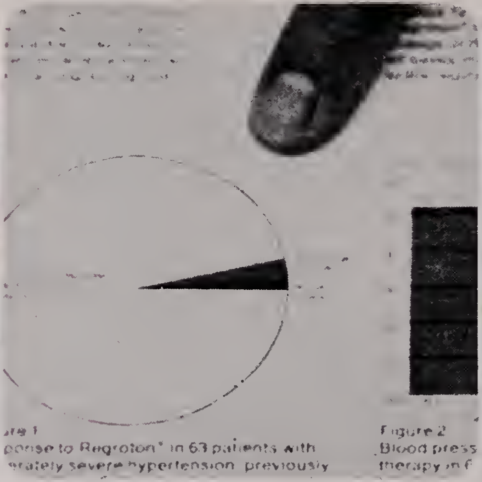
What an opportunity for reviving a noble tradition, for honorable, deserving, self-sacrificing gentlemen!

What's new at Geigy? Regroton, Doctor. For high blood pressure.

Not *another* reserpine-diuretic combination!

Certainly. Regroton has outperformed other combinations.

Says who?



Says this 2-year study by Finnerty.

What's the dosage?

Regroton
Regroton
Geigy

Just one tablet with breakfast.

Sounds ideal!

That's what they say.

Composition: Each tablet contains chlorthalidone, 50 mg., and reserpine, 0.25 mg.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: Discontinue 2 weeks before general anesthesia, 1 week before electroshock therapy, and if depression or peptic ulcer occurs.
Precautions: Reduce dosage of concomitant antihypertensive agents by one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take particular care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side Effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.

Availability: Bottles of 100 and 1000 tablets.
Average Dosage: One tablet daily with breakfast.

Hemochromatosis*

THE ARTICLE on hemochromatosis by Watson and Murray* is noteworthy since these authors express their views without hesitation on the most sensitive and controversial issues in the pathogenesis of the disease. They point out that although Bell, in 1944, found varying amounts of hemosiderin in the livers of patients with cirrhosis and diabetes, he did not call these true hemochromatosis. They also refer to Bell's discussion of a type of hemochromatosis associated with severe anemia in patients who had not received a significant number of blood transfusions. In 1954, we emphasized this type of "secondary hemochromatosis" associated with chronic anemia, which is now well recognized as being distinct from the primary form.

Watson and Murray without question accept the concept that there is a primary type of hemochromatosis and that the hemochromatosis in some of these cases is hereditary. These authors are perhaps the first to strongly refute the concept of MacDonald, who believes that there are no familial or genetic relationships and who has proposed that idiopathic hemochromatosis is a variant of portal cirrhosis with an alcoholic or nutritional cause. Watson and Murray lucidly present the available data, pointing out the reported low incidence of alcoholism as compared to MacDonald's figure of 85 per cent in the Boston series. Certainly, the opinions expressed by Watson and Murray are similar to my observations of 55 patients living mainly in the central United States in whom alcoholism was noted only in a minor percentage and the use of wine, especially, was rare. Our experience reveals that approximately 50 per cent of patients with primary hemochromatosis have "normal" liver function tests, which certainly is a contrast to the group reported by MacDonald in which jaundice was found in 39 per cent. In primary hemochromatosis, jaundice is exceedingly rare except when complicated by a hepatoma. The issue of fatty liver as reviewed by Watson and Murray agrees with my own views; in my experience this is a rare finding in primary hemochromatosis, even with severe diabetes. The observation of heavy deposition of iron in the cirrhotic liver after portacaval shunts is commented on by Watson and Murray, who include a case report of their own. Dr. Bell might have commented on MacDonald's series by a summary in his textbook in 1947 as follows, "Moderate amounts of hemosiderin are frequently found in the liver in ordinary cases of portal cirrhosis, and sometimes the degree of pigmentation approaches that which we are accustomed to consider characteristic of hemochromatosis." This latter group might be called the "MacDonald type" and, as mentioned by Watson and Murray, could be considered a form of acquired hemosiderosis in contrast to primary hemochromatosis.

An excerpt from MacDonald's article, "since iron is not the cause of hemochromatosis, but merely colors our livers and our thinking —," expresses his view on the doubtful role of iron in the etiology. The dramatic improvement in the status of some patients with primary hemochromatosis with diminution of liver size and return of normal activity after multiple phlebotomies is evidence of the pathologic effects of large amounts of iron in the body.

Fatal Neoplasms

A CAREFUL analysis has been made of the frequency, types, and age and sex distribution of fatal neoplasms diagnosed at necropsy at the University of Minnesota in a 51-year period. Although Dr. Robert Hebbel* thoughtfully discusses the limitations of a study of this type, many workers consider data of this kind superior to that obtained from other sources. Certainly this report appears to reflect accurately the trends of fatal neoplastic disease in a large metropolitan area; most of the findings confirm commonly held concepts of neoplastic disease. Although the data were not subjected to statistical analysis, an increased incidence of lung cancer in men was definitely observed in the later years covered by this study. The over-all high incidence of leukemias, lymphomas, and gliomas is worthy of note.

Allergy and Purpura

SOME OF the difficulties in demonstrating allergic mechanisms in disease of man are described by Bowie and Hagedorn in a discussion of allergic aspects of purpura elsewhere in this journal.* In each of the major types of allergic purpura there are differences of opinion as to whether allergic mechanisms operate and, if so, as to the exact nature of the altered response.

Anaphylactoid purpura, once considered to be clearly related to streptococcal infection, is now thought to represent a form of delayed hypersensitivity to a wide variety of infections, as well as to many other agents, including foods, drugs, insect bites, etc. Studies also suggest that in some instances it may represent a type of autoimmune response to vascular endothelium. The exact role of these various agents is not established.

The role of allergy and immunity in idiopathic thrombocytopenic purpura is even more widely disputed. Opinion varies from the suggestion that it should be renamed autoimmune thrombocytopenic purpura to a denial of autoimmunity as an etiologic factor. It is clear that something in the blood of patients with idiopathic thrombocytopenic purpura depresses platelet counts in normal persons, but it is less clear that this represents an antigen-antibody reaction. Many techniques for demonstrating antibody give negative results in patients with idiopathic thrombocytopenic purpura and there are reasons to question results from techniques which have been said to give positive results. Whether these facts argue against an immunologic basis or are merely a reflection of the inadequacy of testing methods cannot be answered at this time.

Finally, the pathogenesis of drug-induced purpura is not much clearer. It appears that some drugs, not in themselves antigenic, bind to serum protein, and the combination is thought to have antigenic specificity. This is considered to be the mechanism of quinidine-induced thrombocytopenia and has been proposed by some as the mechanism for chlorothiazide-induced thrombocytopenia.

A wide variety of agents are related in some way to the clinical manifestation purpura, but the exact nature of these relationships is not always clear.

St. Louis Park, Minnesota

the problem: diabetic . . . overweight . . . unresponsive to diet alone

the answer: ". . . if dietary control seems to be unsatisfactory . . . [and] if the patient is overweight . . . our first choice is phenformin [DBI] since this is the only oral hypoglycemic agent commercially available at present which does not promote fat deposit."[1]

". . . with phenformin [DBI] there may be less preferential stimulation of fat synthesis in the obese, diet-resistant diabetic, favoring both blood sugar and body weight control."[2]

to manage the stable adult diabetic who is overweight and unresponsive to diet alone

DBI® DBI-TD

tablets 25 mg. **timed-disintegration capsules 50 mg.**

BRAND OF PHENFORMIN HCl

DBI together with a proper diet usually affords effective control in the overweight ketoacidosis-resistant diabetic . . . reduces high blood sugar and elevated serum insulin levels, and encourages gradual weight loss toward normal.[3] For the ketoacidosis-prone diabetic, however, insulin is still the essential hypoglycemic drug.

side effects: Gastrointestinal, occurring more often at higher dosage levels, abate promptly upon dosage reduction or temporary withdrawal. **precautions:** Occasionally an insulin-dependent patient will show "starvation" ketosis (acetonuria without hyperglycemia) which must be differentiated from "insulin-lack" ketosis which is accompanied by acidosis, and treated accordingly. Lactic acidosis has been reported in nondiabetics and diabetics treated with insulin, with diet, and with DBI. Question has arisen regarding possible contribution of DBI to lactic acidosis in patients with renal impairment and azotemia and also those with severe hypotension secondary to myocardial or bowel infarction. Periodic B.U.N. determinations should be made when DBI is administered in the presence of chronic renal disease. DBI should not be used when there is significant azotemia. Any cardiovascular lesion that could result in severe or sustained hypotension, which may itself lead to development of lactic acidosis, should be considered cause for immediate discontinuation of DBI at least until normal blood pressure has been restored and is maintained without vasopressors. Should lactic acidosis occur from any cause, vigorous attempts should be made to correct circulatory collapse, tissue hypoxia, and pH. **contraindications:** Severe hepatic disease, renal disease with uremia, cardiovascular collapse. Not recommended without insulin in acute complications of diabetes (metabolic acidosis, coma, severe infections, gangrene, surgery). **pregnancy warning:** *During pregnancy, until safety is proved, use of DBI, like other oral hypoglycemic drugs, is to be avoided.* Consult product brochure for full information.

Letter to the Editor:

It distresses me to see that, in spite of overwhelming evidence that nobody can afford to smoke, many still keep on smoking. Not many are really making a determined effort to stop this exceedingly dangerous habit. Everybody should try to quit and nobody with good intelligence will start the habit, now that the results of years of research have at long last been well publicized. Years ago I called smoking an addiction, but until recently other doctors were not in agreement with me.

For five years prior to 1938, while studying in the Barnard Free Skin and Cancer Hospital of St. Louis and in the New York Skin and Cancer Hospital, I took smoking histories on all cases diagnosed cancer of the lungs. Earlier, I had been for 2½ years just after World War I a chest patient in army and civilian hospitals where I saw a number of associates and good friends die of lung cancer. This caused me to be intensely interested in whether lung cancer was directly related to smoking.

I was forced to conclude from my five years of smoking histories on lung and heart cases even before 1938 that everyone who smokes at all should have a fear of lung cancer, heart disease, and cancer of the lip, throat, mouth, larynx, epiglottis, and esophagus. Those who had these cancers were almost without exception smokers.

For over 25 years now I have with too little success tried to convince the reading public that nobody can afford to smoke. The greatest resistance comes, I am afraid, from smoking publishers and editors and from those who successfully promote smoking through their newspaper.

I have often felt like a lamb bleating in the face of a Minnesota blizzard.

Adrian H. Scolten, M.D.
Portland, Maine

The Editor's Soliloquy

No, Thanks

In popular magazines one often reads of a new way to quit smoking, or of a diet for those who cannot reduce, or of a pattern of life for those who drink too much, or of a method of correcting bad habits, and of a thousand and one other things designed to eliminate our ever-present human dissipations.

Do we need these props? Is it not enough to know that intemperance of smoking, overeating, alcoholism, bad habits, and all of these excesses we humans keep trying to curb, are bad for our health? Does any other member of the animal kingdom indulge in excesses to the detriment of its health? When our marvelously constructed physiologic body finally succumbs to cancer of the lung (tobacco), or when the liver gives up and becomes cirrhotic (alcohol), or when the blood vessels become arteriosclerotic (overeating), is it not possible or even probable that these diseases developed because we didn't have the courage to say "No" — without compromise or capitulation? Do we need a *new* way of saying no: a new inflection, a new posture? Why not just try saying politely but firmly, *"No, thanks."*

Curbstone Consultation

Varicose Ulcers

QUESTION: How do you treat varicose ulcers of the leg?

ANSWER: The basic principles of treatment consist of cleanliness and elevation of the leg or compression by sponge rubber and elastic dressings when the leg is in the dependent position. Local and systemic antibiotics are sometimes needed along with warm wet packs, elevation, and bed rest and even hospitalization in the infected far advanced type of ulcer. An intelligent patient can usually take care of the leg on an ambulatory basis. At times because of the patient's inability to care for the lesion a judiciously and carefully applied gelcast boot with changes weekly or more frequently will effect reduction in size of the ulcer. Surgical treatment of the varicosities and even skin grafting may be necessary at times. The problem requires patience and understanding of the underlying pathology by both patient and physician.

Asymptomatic Pulmonary Nodule

QUESTION: What would you do with a male patient fifty-four years of age who had an asymptomatic pulmonary nodule approximately 2 cm. in size noted on the last chest roentgenogram? Previous chest roentgenograms demonstrate that the nodule was present although perhaps slightly smaller two years prior to the last roentgenogram.

ANSWER: This patient presents the classical problem of the coin lesion. Large studies have shown that if the coin lesion contains calcium and especially if the calcium is dense or concentric, the possibility of this being a peripheral carcinoma is remote. However, in coin lesions that do not demonstrate any evidence of calcium on laminography, approximately 50% in males over fifty years of age will prove to be carcinomas. Even though this lesion has been present for two years this is not inconsistent with a peripheral carcinoma, as X rays have shown lesions present as long as seven years which were actually peripheral carcinomas. Therefore, this individual should have further studies in the form of laminography, exfoliative cytologic studies, bronchoscopy (although this is not to view the lesion but rather to study the tracheal bronchial tree in detail to rule out other lesions). If the lesion is without calcium an exploratory thoracotomy is indicated.

To cure nine out of ten neuroses, take hard work in heavy doses.

Fracture–Trauma Conference

Immobilization in Fractures of the Fingers

What appear to be relatively minor fractures of fingers can sometimes result in rather markedly severe deformities and limitations of hand function. The primary concern of the surgeon in treating fractures of the hand is to obtain good function of the hand subsequent to treatment. It is especially important to be careful to avoid limitation of motion in joints that are not involved in the fracture itself. In addition, it is important to carefully avoid rotational deformities or angulation.

Fractures of this type in growing children differ somewhat from those in adults in that deformities will often correct themselves by the normal growth of the bone. This is especially true of angulatory deformities in which the angle of the deformity is in the same plane as the angle of motion of the adjacent joints; it is also partially true of angular deformities in the opposite plane. Rotational deformities, however, will not be corrected by growth.

In treating fractured phalanges, the best method of treatment is usually to reduce the fracture under anesthesia and then hold the injured finger along with its adjacent finger or fingers in the "position of function," or as is sometimes called, the "position of rest." Rotation can be controlled by being sure the immobilized digit points toward the carpal navicular. If the fracture is unstable in this position, then internal fixation with Kirschner wires or Steinman pins should be used. The pins can usually be placed in a crossed fashion over the fracture site without involving the adjacent joints. Occasionally, a pin in the intermedullary canal will immobilize the fracture better.

Utilizing skin traction, pulp traction, or skeletal traction for a fracture of the phalanx is ordinarily not a good choice of treatment. The reason for this is that, despite the fact that the traction will often provide good immobilization as well as excellent alignment, it may result in limitation of motion of adjacent joints. It is impossible to mobilize the adjacent joints of the hand while the finger is in traction. In addition, it is somewhat difficult to hold the finger in the ideal position of rest during immobilization. There is also the possibility that the pull of the traction through the adjacent joints may result in over-stretching and scarring of the capsular structures of the joints not involved in the injured area.

Continued

When the internal fixation method is used, the pins can be placed in such a fashion that all the adjacent joints can move. As a result, motion can be started much earlier. Ordinarily, the small pins will be removed after the fracture is healed.

The time required for immobilization of a fracture in the hand is determined as in other parts of the body by the age of the patient and the type of fracture involved. A youngster will ordinarily heal one of these fractures more quickly than an older patient. A transverse, undisplaced fracture will heal more quickly than a comminuted or spiral oblique fracture.

It is necessary to follow these fractures closely with X rays at frequent intervals. When the fracture shows evidence of adequate progression of healing, early motion of the adjacent joints of the finger and hand should be begun. When the fracture is solid clinically and by X ray, active range of motion in the involved parts should be instituted immediately. Only after the fracture has completely solidified and all edema and soreness has subsided, should passive range of motion of the fingers be used.

Case Report

This is a report of a 17-year-old patient from Hennepin County General Hospital who sustained a fracture-epiphyseal separation of the base of the proximal phalanx of his ring finger. The fracture was initially treated and reduced by utilizing skeletal traction in the middle phalanx of his finger. The forearm and wrist were then immobilized with a cast, and traction was applied from the finger to the volar aspect of the cast. The finger was held in acceptable position. The reduction of the fracture-epiphyseal separation in the traction was excellent. The patient also had a fracture of the base of the proximal phalanx of the fifth finger of the hand which was immobilized in the position of rest on a volar splint.

After four weeks, the traction was removed and the finger was begun on active range of motion.

The patient was seen ten weeks after the fracture, and X ray showed healing of the fracture in excellent position. Function of the hand, however, was unsatisfactory! The patient had a 90-degree flexion contracture of the *proximal interphalangeal joint* of that finger. It is important to note that the injury did not involve this joint and that, in fact, it involved the opposite end of the proximal phalanx.

Discussion

This case demonstrates that despite excellent reduction and adequate immobilization for the proper period of time in the proper position, the traction method of immobilizing fractures of the phalanges should be avoided unless no other method is available. The present fracture could better have been treated with closed reduction and pinning of the epiphysis with two small crossed wires.

It should also be added that the proximal interphalangeal joint is the most sensitive and delicate joint in the hand, and unnecessary immobilization or traction of this joint should be avoided whenever possible.

Tumor Conference

Villous Adenoma with Electrolyte Imbalance

The first clinical description of a villous tumor was written by Timothy Holmes in 1861.[1] More recently, an association has been demonstrated between these tumors and profuse fluid and electrolyte imbalance. One of the first descriptions of this relationship was written by McKittrick and Wheelock in 1954.[2] In 1961, Davis[3] reviewed the 22 known cases of secreting villous tumors. Since that time a few additional case reports of villous tumors with electrolyte disturbance have been reported.

The following case, a typical example of a secreting villous adenoma, is reported because of the clinical importance in recognizing this syndrome, and because of the apparent rarity of the tumor.

Report of Case

A 69-year-old white female was admitted to the University of Minnesota Hospitals for the first time with the complaint of frequent bowel movements. Approximately five years prior to her admission she first noticed the onset of increasing frequency of bowel movements. She also noticed that with her bowel movements she passed a great volume of clear liquid and occasionally clear liquid alone. These symptoms had increased in frequency until she was having about ten movements a day with rectal urgency. Two months prior to her admission she had developed chills, fever, nausea, and vomiting and was thought to have a rectovesical fistula. Just prior to her admission she had noted profound weakness and stated that she drank a great deal of water and felt thirsty most of the time.

The *physical examination* was unremarkable except for the proctoscopic examination which revealed a large papillary tumor beginning at 9 cm. and which completely filled the bowel lumen at 11 cm.

Numerous *biopsies of the lesion* through the proctoscope revealed adenomatous rectal mucosa histologically. The barium enema revealed a large filling defect on the posterior wall of the rectum and distal sigmoid measuring about 13 cm. in length, which was interpreted as suggestive of malignancy but possibly representing a very large villous adenoma.

Blood chemistries on admission revealed a potassium of 3.0 mEq./L., sodium of 142 mEq./L., chloride of 103 mEq./L., carbon dioxide of 32 mEq./L., and blood urea nitrogen of 33 mg. %. The total serum proteins were 6.4 gr. %. Samples of rectal fluid were collected and found to contain 78 mEq./L. of potassium, 88 mEq./L. of sodium, and 127 mEq./L. of chloride, although the normal average values are potassium 12 mEq./L., sodium 3 mEq./L., and chloride 2 mEq./L. The initial specific gravity of the urine was 1.027. The remainder of the laboratory and radiological examinations were within normal limits.

Continued

The patient's fluid and electrolyte balance were restored employing parenteral and oral routes, following which the patient was operated upon for excision of the tumor. At surgery the tumor was palpated in the distal sigmoid colon as a soft velvet-like mass. A segmental resection of the sigmoid colon with a low anastomosis at the level of the levator ani muscles was carried out.

The *specimen* measured 30 cm. in length (Figure 1). There was an annular soft tumor mass beginning 2 cm. from the distal end of resection and extending 14.5 cm. circumferentially along the bowel. The surface was covered with soft villous structures measuring up to 2 cm. in thickness. The margins were sharp at both extremities. Histologically the tumor was formed of greatly thickened layers of mucous membrane covering thin fibrous stalks (Figure 2). The mucosal glands were greatly elongated and were lined by tall mucus-secreting cells. The stalk showed no evidence of invasion in any section. There was no tumor in the 22 lymph nodes examined. The patient had an

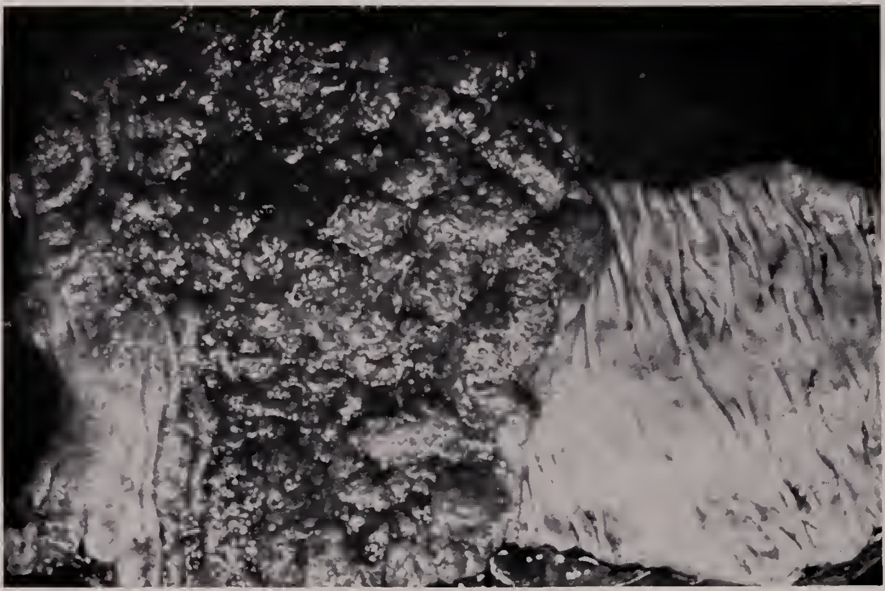

Fig. 1 — Photograph of the gross tumor.

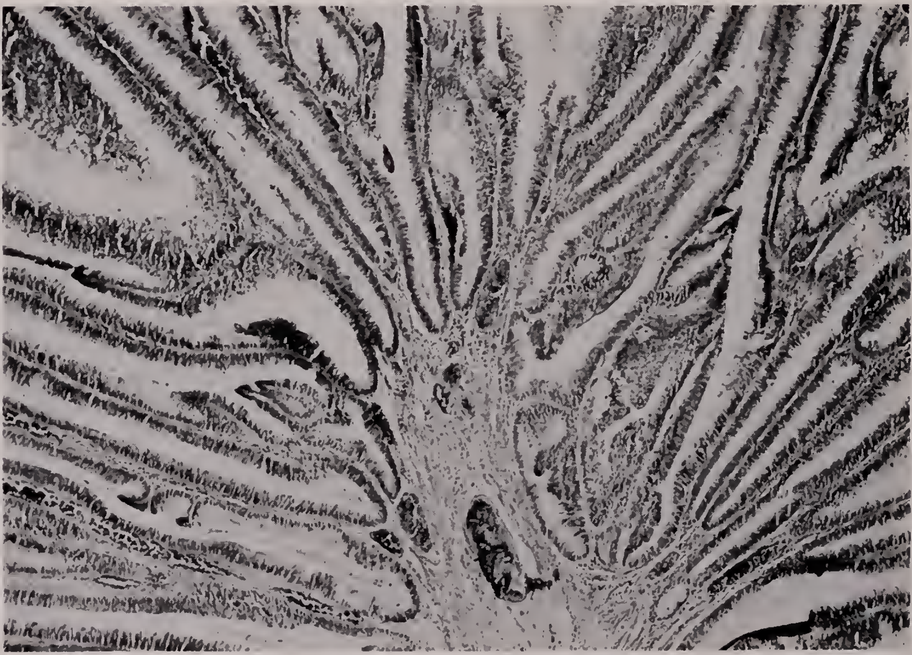

Fig. 2 — Photomicrograph of the villous adenoma (x25) demonstrating finger-like projections arising from a fibrous stalk.

uneventful postoperative course and has had no evidence of recurrence 1.5 years following surgery.

Discussion

Villous tumors account for 1%-3% of surgically removed neoplasms from the colon and rectum. Most are located in the rectum and sigmoid colon.[4]

All villous adenomas produce mucus, but the volume is usually inadequate to produce the symptom of pseudodiarrhea early in the course of the disease. The ability to compensate for the loss of fluids and electrolytes may extend over many years until the tumor enlarges sufficiently, intake is decreased or fluid loss increased to the point where the compensatory mechanisms are ineffectual. At this point, anorexia, weight loss, vomiting, muscular weakness, and severe thirst become prominent. If the patient's course is uninterrupted by treatment, mental confusion, shock, and death may soon follow.

The average duration of symptoms is over five years, and electrolyte imbalance appears to be a late complication.[5] The volume of fluid produced seems to be correlated with the size and surface area of the tumor and to the activity of the surface cells. The area is greatly increased by the convolutions of the frondlike projections inherent in the villous tumor.[3] The rectal fluid appears to be secreted by the cells of the tumor rather than a simple transudate. Shnitka[6] has demonstrated that the average potassium concentration of the rectal fluid is 13.2 times the concentration in serum, though the sodium and chloride approximate serum levels suggesting active secretion of potassium by the cells of the villous tumor. Concurrent depletion of potassium, sodium and chloride with elevation of the BUN and urine specific gravity is the usual picture.[3] The serum proteins are also often depressed, owing to proteinous content of the rectal fluid. This fluid may contain up to 5 gr. of protein per 24 hours.[7]

Symptoms

The most prominent symptom is the profuse rectal discharge passed separately from stool, giving rise to the characteristic pseudodiarrhea.[3] Although the normal water loss in the stool is 100-200 cc. per 24 hours, volumes of up to 3-4 liters per 24 hours can occur, giving rise to the syndrome of dehydration, hypokalemia, uremia, and even death if the electrolyte depletion is not treated.[8] The less frequent symptoms include bleeding, prolapse and intussuception of the tumor, and tenesmus.[3] These tumors are rarely obstructive and are often not palpable by digital examination because of their soft and velvet quality. The barium enema is helpful, especially if the lesion is beyond the reach of the proctoscope.

Malignant Degeneration

Villous tumors have a tendency to undergo malignant degeneration; the incidence ranges from 10%-100% in various series, a discrepancy resulting largely from differing criteria. Biopsying the lesion through the proctoscope is unsatisfactory for, as Dockerty[9] stressed, a carcinoma can lurk in a fold of the tumor and not be found.

Treatment

Treatment consists of restoration of the fluid and electrolyte balance, although this will be difficult to maintain prior to the removal of the

Continued

secreting tumor. Employing whatever procedure is required, complete excision of the lesion with a margin of normal tissue should be carried out as soon as the patient's condition permits.[3] If the lesion is malignant, a cancer operation should be performed.

The Penalty of Overweight

Individuals who are overweight suffer from one-fourth to three-fourths excess in mortality. The hazard percentage of obesity can roughly be stated by the same number as the pounds of overweight. Ten pounds of overweight suggests ten per cent increase in the mortality. Twenty pounds overweight suggests twenty per cent increase in the mortality, etc.

Epilepsy is a major national health problem — with more victims last year than cancer and tuberculosis combined, according to The Epilepsy Foundation. For facts about epilepsy write to: The Epilepsy Foundation, Washington, D. C., 20005.

Clinical Path Conference

Back Pain and Herpes Zoster

Report of Case

A 64-year-old white man registered at the Mayo Clinic in May of 1958 and was admitted to the hospital. Six days previously he had developed sudden, severe sharp pain in the region of the seventh thoracic vertebra. The pain was constant and continued until the time of his admission.

The patient had had the onset of backache involving the thoracic region of the spine in the fall of 1957. He had lost 10 pounds since that time. Although he had a nonproductive morning cough, he had experienced no hemoptysis.

Review of symptoms was essentially within normal limits except for a history of duodenal ulcer in 1957.

Physical Findings

At the time of admission, the blood pressure measured 162 mm. Hg systolic and 78 diastolic (162/78), and the pulse rate, 120 beats per minute. A sebaceous cyst measuring 1.5 cm. in diameter and 1.0 cm. high was felt in the right occipitoparietal region of the scalp. Coarse rales were heard on inspiration in both bases of the lungs. There was no visceromegaly. The prostate gland was enlarged, grade 2, and considered to be benign. Deep tendon reflexes and peripheral pulses in the lower extremity were within normal limts. A vesicular eruption was observed over the back along the route of the right seventh thoracic nerve. Exquisite pain was elicited by light touch over the seventh thoracic vertebra.

Laboratory Findings

Blood hemoglobin measured 12.2 gm. per 100 ml. Erythrocytes numbered 4,080,000 per cubic millimeter of blood, and leukocytes numbered 5,000. A differential leukocyte count revealed 79.5 per cent neutrophils, 12.0 per cent monocytes, and 8.5 per cent lymphocytes. The sedimentation rate was 88 mm. in 1 hour (Westergren). Review of the peripheral blood smear revealed rouleaux formation, grade 3, with toxic polynucleosis. Total serum proteins measured 11.0 gm. per 100 ml. and serum globulins, 8.17 gm. Values for serum calcium, phosphorus, and alkaline phosphatase were within normal limits. Roentgenograms of the chest revealed emphysema of both lungs with probable bronchiectasis at the bases; osteolytic lesions were evident in the eighth rib on the right, posteriorly. Roentgenograms of the head revealed multiple osteolytic lesions of the skull.

Clinical Course

The patient continued to complain of pain for two days after his admission to the hospital. His cough progressed and became more productive. On the third day of hospitalization, new herpetic lesions were observed along the routes of the fifth and eighth thoracic nerves. In addition, similar lesions appeared on the face. The patient subsequently became quite drowsy and on the fourth day of hospitalization was found to be in shock. There were marked rales and rhonchi over both lungs. Despite supportive measures, the patient died.

Continued

Discussion of Case

Murray N. Silverstein, M.D.*

In summary, we have for consideration the story of a patient who had severe back pain and a vesicular skin eruption. Coupled with this, he had constitutional manifestations. Laboratory studies revealed an elevation of the sedimentation rate, marked rouleaux formation on the peripheral blood smear, and hyperglobulinemia. It was my impression on seeing this patient that he had multiple myeloma associated with herpes zoster.

Multiple Myeloma vs. Pain

Of the patients with multiple myeloma who were studied at the Mayo Clinic by Doctors Bayrd and Heck, roughly 85 per cent presented with pain. The outstanding site of pain, of course, was the region of the vertebral column; for, since the bony lesions of myeloma are primarily osteolytic and osteoporotic, collapse of vertebrae is quite frequent.

Protein Electrophoretic Pattern

The blood picture in myeloma can be quite variable. Approximately 80 per cent of patients will have anemia at some stage of their disease. Some 35 per cent of patients studied at the Mayo Clinic have had leukopenia on first observation. Serum protein electrophoresis has been diagnostic in at least 65 per cent of our patients, and in 50 per cent, Bence-Jones protein has been found in the urine. Consequently, study of protein electrophoretic patterns of the blood and urine of patients with myeloma should yield positive results in about 95 per cent of cases. Biopsy of bone marrow should be diagnostic in all cases of myeloma except for those few patients who have so-called solitary extramedullary myelomas.

Herpes Zoster with Myeloma

The association of herpes zoster with myeloma is quite infrequent in our experience. We have seen herpes zoster complicating, or associated with, lymphomatous processes in about 8 per cent of our patients with lymphoma. This has been most frequent in the Hodgkins group of lymphomas.

A study of mineral metabolism in myeloma has revealed that about 36 per cent of our patients have had hypercalcemia. A recent review by Dr. Dillman and myself has shown that alkaline phosphatase is elevated in about 14 per cent of patients with myeloma.

An examination of the bone marrow was performed in the case under consideration. The marrow was found to be cellular, and many myeloma cells were present.

The patient had a most unusual clinical course for multiple myeloma, particularly with respect to the complicating herpes zoster. It was our clinical impression that the herpes zoster became disseminated and that the final event in the patient's illness was the further complication of pneumonia.

Jack L. Titus, M.D.**

Myelomatous lesions were present in the spine, ribs, and skull. Histologically, these were composed of sheets of large cells with abundant basophilic cytoplasm, large eccentrically situated nuclei with clumped chromatin and prominent nucleoli, occasional mitotic figures, and occasional binucleate and giant forms. The bone marrow in uninvolved regions was slightly hypercellular, but otherwise normal.

**Section of Experimental and Anatomic Pathology.

Skin Lesions

Numerous hemorrhagic papules and vesicles covered the skin diffusely; in some areas they were confluent. The vesicular component of the lesion was most marked over the right lower part of the chest. The skin lesions were intraepidermal vesicles in various stages of development; most were composed of epidermal cells showing "ballooning degeneration" with eosinophilic intranuclear inclusions, proteinaceous fluid, and inflammatory cells.

The Lungs

Fibrinous pleuritis and a right pleural effusion (300 ml.) were present. The lungs were markedly edematous and congested (total weight 2020 gm.) ; they contained foci of early bronchopneumonia.

Other Findings

Multiple acute ulcers were present in the stomach, duodenum, colon, and gallbladder. The surface of some of the necrotic ulcers contained epithelial cells with intranuclear inclusions, and in some sites, numerous inflammatory cells were seen throughout the muscular wall.

In some focal areas of acute hemorrhagic pancreatitis, intranuclear inclusions were present. Tiny abscesses were observed in the adrenal cortex and the liver.

Some nerve ganglia showed perivascular cuffing with inflammatory cells, degenerative changes of ganglion cells, and severe congestion or even hemorrhage. No inflammatory lesions were found in the brain, although small capillary hemangiomas were present.

Anatomic Diagnoses

The major anatomic diagnoses were (1) multiple myeloma involving the skull, ribs, and spine, and (2) herpes zoster with visceral dissemination.

Dr. Silverstein

Dr. Martin, would you comment on herpes zoster as an infectious disease, its relationship to chickenpox in childhood, and some of the complications that the illness may produce?

William J. Martin, M.D.*

Chickenpox

Bokay, in 1893, noticed that children exposed to adults with herpes zoster might develop varicella. Morphologically, no consistent differences are seen between the changes induced in cultures of human tissues by the agent of chickenpox and that of herpes zoster. Complement-fixation, fluorescent antibody, and neutralization procedures have shown no significant antigenic differences between the two viruses.

The varicella-zoster virus is highly host-specific and has been trans-

mitted experimentally only to man. The insusceptibility of common laboratory animals to varicella-zoster virus has hampered etiologic investigations; but it provides a useful characteristic in differential diagnosis, since the viruses of herpes simplex and of variola (smallpox) may be propagated in the embryonated hen's egg and in various animals.

The majority of patients with herpes zoster give a history of a previous attack of chickenpox in childhood. Also, herpes zoster is more common in persons who are physically exhausted or who have an underlying debilitating disease. Herpes zoster following trauma such as spinal puncture, or associated with a spinal-cord tumor, lymphoma, or lymphatic leukemia, has suggested the possibility that the virus may remain dormant in the tissues for long periods of time. Since the viruses of herpes zoster and of chickenpox are similar, if not identical, it has been postulated that one virus can cause different diseases in the susceptible and partially immune subject. In other words, chickenpox may constitute the response of the nonimmune host and herpes zoster, that of the partially immune person.

Complications of Herpes Zoster

Some of the complications of herpes zoster include secondary bacterial infection of the ruptured vesicles, which is common. *When the nasociliary branch of the gasserian ganglion is involved,* the cornea, sclera, or ciliary body may be permanently damaged. Disease of *the geniculate ganglion* may lead to lesions of the concha of the ear, the external auditory canal, and the soft palate and loss of taste (Hunt's syndrome) ; this is often accompanied by paralysis of the seventh nerve. As in the case at hand, in 2 to 5 per cent of patients a generalized vesicular eruption simulating chickenpox occurs (zoster generalisatus). In such cases, dissemination generally takes place within a few days after appearance of the initial lesions, and the cutaneous involvement is often so extensive as to include the palms and soles. The *eyes, mucous membranes, and lungs* may be affected. *Headache and meningismus* are fairly frequent, and up to 50 per cent of patients have leukocytosis of the spinal fluid. A more serious complication is so-called zoster myelitis which was first described in 1876. Encephalitis or encephalomyelitis also occurs and has caused death. In these more serious cases, the cerebrospinal fluid may contain large numbers of leukocytes and high protein and low glucose concentrations. It is not known if zoster encephalomyelitis reflects direct extension of the virus or an autoimmune mechanism. Postherpetic neuralgia appears to be limited to the aged with arteriosclerosis.

Dr. Silverstein

Dr. Martin, we know that patients with myeloma have defective defense mechanisms. The proteins that these patients make have very poor quality, in regard to their effectiveness as antibodies. Would you comment regarding the role that antibodies play in viral infection in general, and would you also comment on the incidence of viral and other infections in malignant disease?

Dr. Martin

Infection with a virus is followed by the development of antibodies to the specific virus, and immunity is correlated with the continued avail-

Continued

ability of these antibodies. Yet it is not known precisely why immunity is not developed to certain viral diseases (herpes simplex) but persists indefinitely to others (mumps). Another oddity is that one cannot produce effective immunity against some viral diseases by means of inactivated viruses (smallpox) but can against others (rabies). It is important to recall that, in contradistinction to immunity, recovery from a viral disease appears not to be correlated with the development of circulating antibodies despite their concurrent appearance, since conquest by the host of the virus takes place at the cellular level.

Herpes Zoster vs. Malignant Disease

We have already noted increased incidence of herpes zoster in patients having spinal-cord tumor and in those having malignant disease, particularly lymphoma and chronic lymphatic leukemia. There are other examples of increased incidence of infectious disease in patients having neoplasia. Twenty to twenty-five per cent of patients with bacteremia due to gram-negative bacilli have underlying malignancy—such as lymphoma or a hematologic disorder—such as multiple myeloma and agranulocytosis. Repeated pneumonia, urinary-tract infection, and bacteremia show an increased incidence in patients with multiple myeloma. The incidence of cryptococcosis is increased in patients having lymphoma, and mucormycosis is fairly common in patients debilitated by malignant disease.

Since the patient at hand developed pneumonia it may be well to say a few words about this complication in victims of multiple myeloma. The increased incidence of this complication in these patients is well known, and while it may result from infection due to various micro-organisms, it is most commonly caused by pneumococci. Incidentally the prognosis in type-3 pneumococcal pneumonia is regarded as being especially guarded, in part at least, because of the frequency with which type-3 infections occur in patients having debilitating underlying diseases such as multiple myeloma. Also, the type-3 pneumococcus possesses an unusually thick capsule, is especially difficult for neutrophils to engulf, and is the pneumococcus most likely to produce pulmonary abscess. In connection with your remarks concerning defective defense mechanisms in patients with multiple myeloma, the resistance of the host to pneumococcal infection is enhanced by specific antibody which not only increases phagocytosis but also retards the spread of bacteria in the tissues. However, recovery is not entirely dependent on the immune response, since antibody is not invariably demonstrated in patients who recover with or without antibacterial therapy.

In regard to the patient under discussion, we noted previously that in cases of disseminated herpes zoster the lungs may be affected.

Dr. Silverstein

Dr. Martin, aside from prophylactic therapy in the form of vaccines, are there any viral illnesses for which effective therapy is currently or potentially available?

Dr. Martin

Treatment with Immune Serum Globulin

Gamma globulin (USP immune serum globulin) has potential use in the management of rubeola, infectious and serum hepatitis, poliomyelitis, and perhaps rubella and varicella. Use of gamma globulin has been advocated in children with leukemia, lymphoma, and those receiving immune-suppressing treatment, such as treatment with steroids or irradiation, when they get chickenpox. Gamma globulin rarely prevents chickenpox, but when administered in doses on the order of 0.6 ml. per kilogram of body weight it may modify the effects of the disease. Gamma globulin may not be totally effective in preventing hepatitis, but it affords protection in the form of reduced clinical severity of the disease for two to six months. Investigators currently are evaluating the use of gamma globulin at the time of blood transfusion as a preventive measure against serum hepatitis. Gamma globulin has been used in attempts to modify or protect against poliomyelitis, but it appears to have no protective value in preventing the disease after an individual has been exposed.

Hyperimmune Gamma Globulin for Mumps

Mumps-specific gamma globulin (hyperimmune gamma globulin) may decrease the risk of development of mumps and, given early in the disease, may reduce the incidence of complications. Use of USP immune serum globulin has no demonstrable effect on the disease.

Hyperimmune Vaccinia Gamma Globulin

Human hyperimmune vaccinia gamma globulin may prevent or modify smallpox if given within 24 hours after exposure. Passive protection may be provided after accidental exposure to vaccinia virus in a patient with extensive lesions of the skin such as eczema or burns. It also may be useful in the treatment of certain complications of vaccination such as vaccinia necrosum.

Hyperimmune Horse Serum for Rabies

An advance in antirabic therapy is the availability of hyperimmune horse serum. In persons with multiple severe bites, particularly about the head and neck, who probably have received large amounts of rabies virus, the incubation period may be so short that vaccination cannot produce immunity soon enough. Use of hyperimmune horse serum may provide passive protection until vaccination has stimulated active immunity. The patient's sensitivity to horse serum should be determined beforehand. In this regard, because of the high incidence of reaction to horse serum, a drive is under way to obtain blood from veterinarians who have had the full course of antirabies vaccine after exposure to rabies. It is hoped that serum obtained from such blood will be sufficiently effective to replace hyperimmune horse serum.

Topical Idoxuridine for Corneal Ulcers

The effectiveness of topical idoxuridine (IDU) in acute, superficial corneal ulcers appears to have been demonstrated, but its usefulness in other herpetic lesions such as those of the skin is less definite; the drug is commercially available. A drug currently under investigation is Cytosine arabinoside hydrochloride (CA), which also appears to be effective locally against herpes simplex and may be synergistic with IDU in antiherpes therapy.

Continued

Treatment for Smallpox Contacts

M-Isatin-β-Thiosemicarbazone (Methisazone), a semicarbazone derivative given orally, is effective in protecting smallpox contacts. The drug may cause nausea and vomiting, but serious toxicity in patients receiving the drug on an investigational basis has not been reported to date. In experimental animals there is some evidence of an hepatotoxic effect. *M*-Isatin-β-Thiosemicarbazone is protective regardless of the contact's vaccination status, but is ineffective once infection is established.

Influenza

1-Adamantanamine hydrochloride (Amantadine), also given by the oral route, may be useful in both preventing and treating influenza. No serious toxic effects have been reported on investigational use of the drug in patients as yet. Amantadine also may have potential use in rubella.

Paolin, a marine glycoprotein having antiviral properties, was originally isolated from the oyster, but it has also been extracted from other marine animals including the clam, sea snail, queen conch, squid, and abalone. The antiviral properties of this new antibiotic have been tested in mice and monolayer rabbit tissue cultures. In mice, a single prophylactic intraperitoneal injection of 2.5 mg. per kilogram reduced the poliovirus mortality rate almost to half of that observed in the control group.

Streptothricin, an antibiotic, is active in vitro against certain viruses causing hepatitis.

Interferon and its antiviral activity currently are the subject of considerable investigation. This natural product, one source of which is mammalian cells, appears to prevent the cells of the host from supporting viral growth, perhaps by inhibiting the cellular synthesis of viral nucleic acids. In experimental animals, viremia will stimulate production of large amounts of interferon, and foreign nucleic acids also will act as endogenous interferon producers. Production of interferon in chickens and mice has been induced by injections of live strains of *Brucella*, but not by heat-inactivated *Brucella*. Statolon, a product of *Penicillium stoloniferium*, is being investigated for its interferon-stimulating potential. As a generalization, interferon is species specific and virus nonspecific. That is to say, chicken-produced interferon fails to protect mice from viruses, and mouse-produced interferon will not inhibit viral infection in chickens. While interferon is generally species specific, there is a notable exception since simian interferon does have some degree of activity on human cells. Interferon is virus nonspecific since fresh cells are resistant not to just one virus but to many. Currently interferon is obtained from cells infected with a virus in a test tube or from experimental animals infected by injecting a virus into the blood. In the latter case, interferon produced in the animal's cells appears in the serum and is obtained by bleeding the host. A future possibility is synthesis of the substance. Theoretically, in the therapy of human diseases of viral origin, the use of nonviral substances, such as either animal or yeast nucleic acids, or of avirulent viruses might result in the continuous production of large amounts of interferon. This approach would have the advantage of eliminating the species barrier and of making the substance available prior to its possible synthesis.

In addition to the aforementioned, numerous other substances currently are being investigated for antiviral activity.

Dr. Silverstein

Dr. Martin, what possible role do you think various forms of therapy may play in the precipitation or dissemination of viral and other infections in patients with malignancy?

Dr. Martin

Again taking bacteremia due to gram-negative bacilli as an example, certain forms of therapy appear to play a role in the genesis of the infection in patients with malignancy. These forms of treatment include surgical and instrumentative procedures and intravenous injections as well as the administration of antimicrobial, antimetabolic, and adrenocorticosteroid agents; the influence of irradiation is less definite. Some of these forms of therapy may play a similar role in other infections, such as mucormycosis, and in certain viral infections as well.

In regard to viral infections, aspiration of cerebrospinal fluid appears to have precipitated herpes zoster. The incidence of herpes zoster also appears to be increased in patients treated with arsenicals.

Several deaths have been attributed to chickenpox in children who were receiving steroids because of rheumatic fever. Use of these agents has been recommended in complicated herpes zoster, but in view of these fatalities in children, steroid therapy in infections due to the varicella-zoster virus would appear to be somewhat hazardous. There is some evidence indicating that steroids may interfere with interferon production. Some investigators have concluded that treatment with adrenocorticotrophic hormone, adrenocorticosteroids, roentgen rays, and radiomimetic drugs appears to increase the possibility of dissemination of the virus in patients with localized herpes zoster.

The Rx in Ancient Medical Manuscripts

"The symbol Rx used today as the prefix of the physician's prescription is not, as is frequently supposed, an abbreviation of a Latin word meaning recipe or compound, but is an invocation to Jupiter, a prayer for his aid to make the treatment effective. It is one of the superstitious elements that has clung to medicine even though its significance has been lost; it persists now merely as a convention."*

It is more likely, however, that the Latin *recipe* was used by the Romans, not as a noun but as the imperative form of the verbo *recipio* — to take.

Substantiation for this is supplied by Webster:

> Rx (L. Recipe.) Take.
>
> Note. — This character is reputed to have been originally the same as ♃, the symbol of Jupiter, which was placed at the top of a formula to propitiate the king of the gods, that the compound might act favorably.

Neuro-Pediatrics Conference

Sturge-Weber Syndrome*

Dr. Robert van Tassel:** This 12-year-old white male is a product of a normal pregnancy which was terminated by a Cesarean section for suspected RH incompatibility. He weighed seven pounds, four ounces at birth and was considered normal, except for a port-wine nevus over the right trigeminal nerve distribution. His developmental milestones in the first year of life were normal.

At 11 months of age, he became quite irritable and had a grand-mal seizure characterized by twitching of the left eye, followed by a focal left-sided convulsion which started in the left hand and arm. The diagnosis of Sturge-Weber syndrome was suspected. An electroencephalogram, pneumoencephalogram and arteriogram were performed, but were felt not to be diagnostic for this syndrome. He was then taken to the University Hospital at Ann Arbor, Michigan, where he was placed on Dilantin and Mebarol, which seemed to decrease the number of left-sided seizures.

He was admitted to the University Hospital at Ann Arbor at age 16 months, for further evaluation, at which time he was having anywhere from three to nine left-sided seizures per day. Physical examination revealed an irritable child with a port-wine nevus involving the right cheek, eye and forehead, and the right megalocornea. Also a left hemiparesis was noted. On the basis of the clinical findings a definite diagnosis of Sturge-Weber syndrome was made; and a recommendation for a right-sided hemispherectomy was rejected by the parents. Skull films taken at this time showed no calcification. The child was placed on Dilantin, Mebarol and Mesantoin, which seemed to control his seizures. The doses of these medications have been varied throughout the years depending on the number of seizures per week, most of these occurring during the day. However, the parents feel that the number of seizures is increasing. Presently the child is on Phenobarbital, 60 mg. T.I.D. and Dilantin, 100 mg. T.I.D.

He has been attending special classes since age six. The family moved

to Minneapolis in the summer of 1962, where he is now attending special classes at Warrington Elementary School.

Family history shows that both parents are living and well, and there are three other living children. The younger sister, age three, has congenital deafness and is being followed at the University Hospitals. One other child died from hydrocephalus, and one sibling was a stillborn.

Review of systems shows that he does have headaches, often preceding and following a seizure. The mother feels he has difficulty with his vision and must squint to look at things which are quite close to him. His hearing appears good; otherwise there are no particular problems.

Physical examination shows an obese child who is somewhat slow to respond. A port-wine nevus is noted in the right trigeminal area (Figure 1) as well as a small port-wine nevus in the occipital region on the right. His pupils are unequal, the right eye being larger than the left, and the fundi are difficult to examine. The left thumb is smaller than the right and there is mild impairment of two-point discrimination and simultaneous extinction on the left. However, no weakness is present on the left. The remaining physical examination is within normal limits, and no pyramidal tract signs are present.

The Evaluation

The child was referred to the University Hospitals by Dr. A. H. Wolf, Minneapolis, for: 1. Control of his seizures; 2. Prognosis and possibility for further educational training.

Mrs. Jessica Swain*

The two older children seem to be mature individuals. The mother appears to be high-strung and works from eight to 18 hours per day. The family moved to Minneapolis from Ohio two years ago in hopes of "starting over." The patient's medical problems appear not to be influencing the present difficulties at home. The family will not consider institutionalization, as they have been told that the child will not live through adolescence. No other social agencies are working with the family, as the mother has refused help from any other agencies.

Dr. Paul Moe**

In the Sturge-Weber syndrome the primary physical finding consists of a facial nevus flammeus (port-wine nevus), usually unilateral, located above and involving one eye (Figure 1). Concomitantly with the facial nevus there are brain and meningeal angiomata on the homolateral side associated with the radiographic finding of calcification (Figures 2 and 3). The cranial calcifications are characteristically "double-contoured" as a result of calcium deposits which follow the folds of the gyri. Cortical calcification is usually not discernible in the first year or two of life and has thus been confusing in making an early diagnosis by the classical radiographic findings.

Convulsions are an almost constant feature of this syndrome and usually occur during the first year of life in those with the more extensive facial nevi, and by two years in the lesser examples. As might be expected, the convulsions are usually focal in nature, involving the contralateral side of the body. The Jacksonian seizure pattern, as noted in this patient, is frequently seen and may be generalized in individual attacks or bouts of attacks. A history of paresis following seizures is unusually high among patients with Sturge-Weber syndrome, probably reflecting the abnormal cerebral vascular supply.

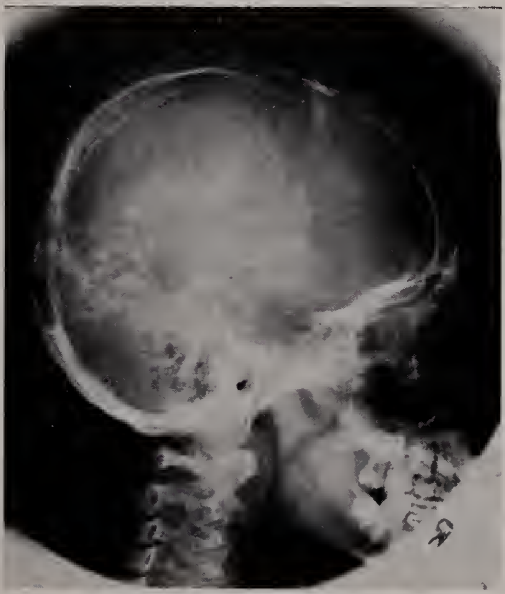

Fig. 2 — Radiograph of skull showing the characteristic "double contour" calcifications of the cortex in the Sturge-Weber syndrome. (Lateral view-right).

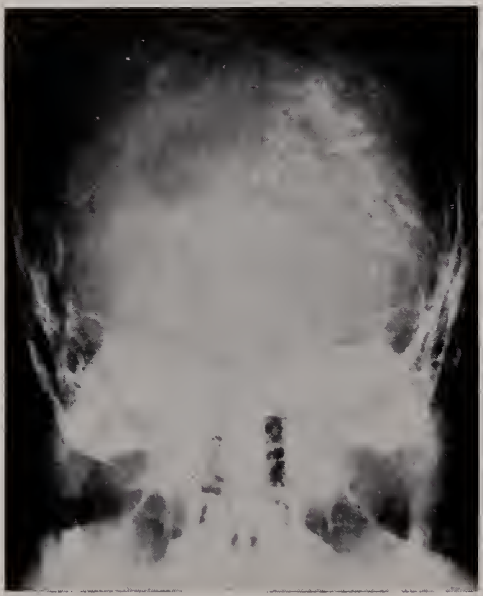

Fig. 3 — Radiograph of skull (A-P view) showing the cortical calcification of the Sturge-Weber syndrome.

Continued

Intellectual deficit is a frequently-associated symptom; the intelligence may deteriorate if convulsions are frequent. The etiology of the retardation is probably due to the abnormal meningeal blood supply on the developing cortex. Pathologically, the affected part of the brain is atrophied, and over this the leptomeninges are thick and contain a network of thin-walled vessels of the venous type. The adjacent cortex and convolutional white matter also contain an excess of similar vessels. During childhood a progressive calcification occurs within the cerebral cortex. Alexander and Norman[1] feel that this calcium deposition is a consequence of some local change in tissue metabolism conditioned in part by the presence of the overlying angiomatosis.

Therapy has been difficult in these patients, particularly in regard to seizure control. Some authors[1] feel surgical intervention with removal of pathological tissue (hemispherectomy) should be performed within two months after birth. A follow-up of 35 patients at the Mayo Clinic[2] reveals that one half of their patients are well with very few seizures. Ten patients are poorly controlled and four have died.

One seizure every three weeks represents good control. The patient should be followed at monthly intervals to regulate his medications.

Dr. ten Bensel

Genetically no familial incidence has been established, and there is equal sex distribution. A recent chromosomal abnormality has been reported, but has not been verified by others.[3,4]

Dr. Ellingson*

Examination of the eye revealed that the patient could see fingers at only two feet. Vision in the left eye appeared normal. On slit-lamp examination of the right eye, dilated vessels were noted in the region on the ciliary body but could not be definitely seen on the conventional funduscopic examination. There was Grade IV cupping present, as seen in glaucoma. The pressure in the right eye was 48 mm. of mercury (normal 20 mm. of mercury or less). This type of glaucoma is considered an open angle glaucoma, and it is not known whether this is due to venous congestion caused by angioma of the choroid or to increased production of fluid within the eye. At the present time therapy should be gauged to prevent a painful eye and to prevent a totally blind one. The child is now on Pilocarpine and an epinepherine derivative to decrease production of fluid within the eye. For the remainder of his life he will have to be on this medication, given four times a day. At present, he is administering his own medication.

Miss Joan Pabst**

The patient was a co-operative, affable child. Poor motor co-ordination and a short attention span were noted, but there was no difficulty in communicating with him. A Stanford-Binet test was performed which showed a mental age of six years and six months for an I.Q. of 58, representing four to six years retardation. It was noted that he had poor facility with numbers but did show some facility in verbal ability and in making judgments in life-situation questions. A Bender-Gestalt test showed significant signs of severe perceptual motor disturbance with evidence of organic dysfunction. However, he was considered to be educable by present standards. There had been no significant deterioration since his last I.Q. test, given in 1962.

---

*Ophthalmologist, University of Minnesota Medical School.

**Clinical psychologist, University of Minnesota Medical School.

Dr. Wentworth Quast*

The child should be gauged also by the level he was functioning at in school, which appeared to be quite low. A school such as Cambridge State School would be optimal in terms of educational opportunity. In this type of situation, if the seizures could be managed and the child placed in a one-to-one relationship with a teacher, he might benefit greatly.

Dr. Frank Lassman**

The child was co-operative but was observed to have a low frustration level and a feeling of hostility. Hearing tests were all normal. Filtered speech, which tests the anterior temporal lobe, was normal. The child could repeat four numbers forward but none backwards. On a verbal-picture test he scored nine years; six months on the Nashville Norms. His visual discrimination was felt to be good, but he had great difficulty with visual memory as well as with motor co-ordination. He had no reading ability, and could not spell his name. He is felt to be educable, particularly in a one-to-one situation.

Dr. ten Bensel

There is concern about the feelings of the mother toward the child; whether or not she has a psychological need to keep the patient at home with her. Secondly, in regard to the school's work with the patient, it is questionable whether they can progress any further with him in the present situation. In view of past refusal to accept counseling from various sources, however, it was felt that another attempt should be made.

Final Recommendations

The primary aim for this patient is counseling for the parents and adequate seizure control. The parents should be advised as to his prognosis, which at the present time appears good, as he has not showed any signs of deteriorating. It is hoped that with better regulation of his seizures further educational attempts may be more successful. However, it is pointed out that control of seizures may not necessarily change matters appreciably in this regard.

The parents should be instructed to contact Hennepin County Child Service Division for counsel in regard to possible institutionalization. Under such a program the child would be awarded state guardianship as a mentally retarded child and placed on a waiting list (which is usually two to three years) for possible institutionalization. If the school is at the end of its educational efforts and is performing only custodial care, and if the mother refuses further consultative help, it is planned to make a recommendation through Court Services, instructing that since other efforts have failed, optimum educational opportunities can be afforded through institutionalization at Cambridge. It is hoped this last step will not have to be resorted to as the other measures should be tried first.

Medical Ethics

Many people overlook one very extraordinary aspect of medical ethics. You see, medicine originated in religion, and as a profession it has retained in its principles some of the religious virtues of self-sacrifice to the suffering of others.

It follows a course that must seem most impracticable to many men of commerce. It is this: A man may invent a mechanical device for the comfort, profit, or pleasure of mankind; manufacture and sell it to his financial betterment, keeping his process secret or protected by patents. He can do all this quite honorably; even if he becomes rich, no one looks at him askance — indeed, quite the reverse. Such is not the case in medicine.

A physician or dentist who seeks and finds a means of alleviating suffering or prolonging life makes his discovery public that all may see and benefit without financial recompense to him. Such a procedure is followed in no other branch of human learning practiced for a livelihood. This obligation which the physician and dentist accept, and enforce, is looked upon as a natural course by all of those people who accept as equally natural quite the opposite course from all other members of society.

Infections of the Urinary Tract

Part I — Some Nosologic and Etiologic Considerations

WILLIAM J. MARTIN, M.D.*
RICHARD D. WAGONER, M.D.*
Rochester, Minnesota

IN THE preceding two decades, advances have been made in the ability to diagnose and treat infections of the urinary tract. Consequently, the physician has available a more accurate and satisfying approach to the individual problem at hand. Although not all infections are amenable to therapy, treatment can prevent further deterioration of renal function in many cases and alleviate symptoms in most cases. Prevention of significant renal injury consequent to infections of the urinary tract remains the primary goal of the physician; early detection of infection, along with judicious management, makes his goal progressively achievable. It is commonly accepted that infections of the urinary tract are second in incidence only to respiratory infections.

Infections of the urinary tract are difficult to discuss since they have varied pathogenesis, symptomatology, and prognosis; consequently an extensive terminology based on various etiologic and clinical nuances has accrued. There are such nosologic entities as septic infarct, renal carbuncle, perinephritic abscess, primary versus secondary infection, ascending versus descending infection, and pyelitis versus pyelonephritis. Whatever the name, the basic disease is infection; the same infecting organisms are common to the various syndromes; and the essential purpose of diagnosis and treatment is eradication of the infection.

For present purposes, this extensive terminology will be avoided, and instead infections of the urinary tract will be discussed from the point of view of the following clinical syndromes.

Clinical Syndromes

Asymptomatic Bacteriuria

While known to be of increased incidence in certain conditions, asymptomatic bacteriuria also seems to occur in persons who otherwise appear to be normal. If infection of the urinary tract is manifested by asymptomatic bacteriuria and can be detected and eliminated, some cases of ultimate renal insufficiency might be avoided. Persons who have asymptomatic bacteriuria may contribute to the discrepancy between clinically recognized infection of the urinary tract and its higher incidence at necropsy. In this regard, chronic inflammatory interstitial lesions of the renal parenchyma (labeled pyelonephritis) may represent processes other than primary bacterial infections, such as those due to various toxic chemical agents, metabolic abnormalities, and vascular changes. A critical question is whether asymptomatic bacteriuria usually leads to

Continued

---

*Section of Medicine, Mayo Clinic and Mayo Foundation.

pyelonephritis or whether pyelonephritis usually arises because previously damaged kidneys become infected, with resultant bacteriuria.[1] In our present state of knowledge, it appears wiser to conclude that urinary infection including renal involvement does or is likely to occur[2] in patients having persistent bacteriuria of significant degree.

Infections

Acute infections of the urinary tract vary considerably in pathology and symptomatology. At one end of the gamut there occurs the so-called simple infection, which commonly is seen in young or middle-aged women. Often it is not associated with detectable underlying uropathy and, being intrinsically a self-limited disease, may respond to minimal medical management. On the other end, there is included such serious states as renal abscess, which may be associated with bacteremia or endocarditis. In most acute infections of the urinary tract, local and constitutional manifestations parallel the degree of urinary infection, but occasionally they may not.

Recurrent infection of the urinary tract often develops in the absence of underlying uropathy or predisposing disease, but such infection should always be excluded by careful urologic and microbiologic investigation. The physician also should attempt to distinguish such recurrent infection from chronic infection in exacerbation, although occasionally the distinction is difficult if not impossible. Recurrences probably reflect reinfection, relapse, and superinfection in decreasing order of incidence.

In chronic infection of the urinary tract, unlike acute simple and recurrent infections, underlying uropathy often is present. The underlying obstructive lesions of the urinary tract may be structural or functional and either acquired or congenital. Such obstruction, with poor drainage of urine, may be attended by varying degrees of dilation of the bladder with trabeculation and hypertrophy, hydroureter, and hydronephrosis. A considerable number of chronic infections are relatively asymptomatic, and some of them may present as asymptomatic bacteriuria. Flare-ups of smoldering and active, but silent, infections may occur, especially in the presence of undetected incomplete urinary obstruction. In contradistinction to the acute process wherein there usually are local and systemic manifestations of infection, the principal findings in chronic disease are likely to be those related to previously sustained renal injury. These latter findings may include proteinuria, abnormal urinary sediment, azotemia, and calyceal changes on excretory urography. Chronic urinary infection is often of insidious onset, since frequently at the diagnosis no history of urinary infection in earlier life may be obtained.[3] Also, patients known to have had multiple attacks of acute infections may not show progression to chronic disease even after many years. Thus, preceding acute urinary infection and chronic pyelonephritis perhaps are not a necessary sequence. However, until more complete data are available, the best empiric approach to the problem probably is tentative acceptance that the earlier and more completely the acute infection is eradicated, the better is the ultimate renal prognosis. Lack of previous diagnosis does not necessarily exclude occurrence; perhaps prior infection presented as an unexplained fever in earlier life.

Etiologic Factors

Uropathogenic Bacteria

In the causation of the infections of the urinary tract, the first necessity obviously is an uropathogenic strain of bacteria. The five most frequently causative ones are (1) coli-aerogenes organisms, (2) Proteus organisms, (3) Pseudomonas organisms, (4) streptococci, usually enterococci, and (5) staphylococci.

Bacterial Source

The theory that most cases of urinary infection reflect entry of bacteria into the tract via the urethra and the subsequent ascent of the organisms to the kidney is being increasingly propounded. The bacteria appear to originate usually in the host's own intestinal tract, except for some strains of Pseudomonas and Staphylococcus, which may be of exogenous origin.

Vesicoureteral Reflux

Theoretically, vesicoureteral reflux on micturition would abet infection of the kidney by the ascending route. Such reflux may be a constitutional characteristic in some individuals but appears to be lacking in most normal persons. Some investigators[4] have said that acute cystitis may produce temporary ureteral reflux and that repeated infections may produce persistent reflux. Thus, actualization of a vicious circle is theoretically possible, wherein recurrent infection may destroy ureterovesical continence and permit consistent hydrostatic injections of infected urine into the kidneys until chronic pyelonephritis is established.[4]

Age and Sex

Infection of the urinary tract is a disease of children of both sexes, women of the child-bearing age, and the elderly of both sexes. It is seldom seen in adult men in middle life. The frequency of urinary obstruction on either a congenital or an acquired basis and the ease of entry of bacteria into the urinary tract are the chief factors in these differences of age and sex. Overt infections of the urinary tract are three times more common in women than in men. Asymptomatic bacteriuria also is more common in females than in males. About two thirds of these infections in women occur before they are 40 years old, and two thirds of those in men occur after they are 40 years old. Despite the higher clinical incidence of infections in women, the disease may be comparatively more lethal in men, as evidenced by the fact that, at necropsy, it is almost equally frequent in the two sexes.

Underlying Uropathy

Numerous structural abnormalities[5] along the urinary tract, such as urolithiasis, strictures, cysts, and tumors, may produce stagnation and consequent infection. Until disproved, the probability of prostatism in men more than 50 years of age who have urinary infection is high. The external genitalia of men should be examined for such abnormalities as pinpoint meatus and phimosis, while women should be examined for pelvic relaxation, infiltration of the bladder by carcinoma, and the like. Underlying uropathy that is most commonly susceptible to surgical correction is found in the very young and in men more than 40 years old. Adequate removal of demonstrated obstructions may bring about cure of infections per se.

Pregnancy

In pregnant women, urinary infections are at least twice as frequent as in nonpregnant women; except for excessive gain in weight, pyelonephritis probably is the most common complication of pregnancy. The flow of urine is slowed by the dilated and distorted ureters, made atonic by the increased secretion of progesterone, and subjected to the pressure of the enlarging uterus; in the last trimester the bladder becomes compressed, resulting in further urinary stasis. Infection is particularly frequent in the last trimester and is common in the puerperium. It is striking that the right side is much more frequently affected than the left in the gravid state. Infection may be more common in negro women than white women. Further, urinary infections are said to be almost twice as common in toxemic as in normal pregnant women.[6] In pregnant women, asymptomatic bacteriuria may occur weeks before frank symptoms of urinary infection, and pyelonephritis of pregnancy probably occurs almost exclusively in women with pre-existing bacteriuria. Approximately 4 per cent of gravid women have bacteriuria, and of this group about one in five develops acute pyelonephritis if left untreated. Kass[7] has found that 0.5 gm. of sulfonamide given daily for one to two weeks during the period of asymptomatic bacteriuria usually prevents acute pyelonephritis in these women. Of pregnant women with bacteriuria, only one third have urinary symptoms; however, symptoms are noted in about half of those with previous episodes, in contrast to only one fourth of those without earlier complaints.[8]

Urethral Manipulation

Infection of the urinary tract follows single catheterization in 2 to 4 per cent of patients, and it develops in almost all pa-

Continued

tients who have indwelling catheters for several days, whether or not antibacterial prophylaxis with chemotherapeutic or antibiotic agents administered systemically is given. A possible exception to this latter generalization is when the catheter can be removed in 72 hours; in such cases systemic antibacterial prophylaxis may be beneficial. In patients requiring prolonged use of a catheter, 0.1 per cent solution of lactic or acetic acid delivered via slow drip into the bladder by an indwelling catheter may reduce the pH of the urine to 5 or less and thereby prevent infection. However, the procedure is somewhat cumbersome, and urine must be released every two hours. Irrigation of the bladder several times daily with chlorhexidine (1:20,000) also has been recommended in patients with indwelling catheters. Continuous use of a neomycin-polymyxin B rinse via a three-way catheter may be even more efficacious in preventing infection and especially in forestalling bacterial invasion of the blood.[9] The three-way instrument has an extra lumen — an inflow tube added to the usual outflow and balloon lumens. The inflow is used to introduce, during 24 hours, a very slow drip of saline (1000 ml.) to which has been added 40 mg. of neomycin and 20 mg. of polymyxin B. Attempts at prolonged systemic antibacterial prophylaxis with agents such as the sulfonamides may serve only to eliminate more susceptible organisms and consequently predispose to infection with enterococci and Proteus, and Pseudomonas organisms which ultimately require more heroic therapy.

Manipulation, including catheterization, of an infected urinary tract may result in bacteremia and sometimes fatal bacteremic shock, if treatment is not given beforehand to control the infection. While this premanipulative antimicrobial therapy may control the infection to the point of disallowing bacterial invasion of the blood, such therapy usually will not eradicate the infection, especially when there is underlying uropathy. If fever occurs after urologic manipulation, both the urine and the blood should be cultured.

The risk of infection from catheterization or other urethral instrumentation varies with the individual situation and the reason for catheterization; but, no matter how carefully executed, these procedures carry the inherent hazard of iatrogenic bacterial contamination and infection. In every case, there is the potential that pathogenic bacteria in the urethra can be pushed into the bladder with the tip of the catheter or instrument. In addition to contaminating the urine specimen obtained, one may, if residual urine is present or if the patient has diabetes, infect the remaining urine and increase the likelihood of postcatheterization urinary infection. Organisms virtually always are recoverable from the distal centimeter of the male urethra and from about half of male urethras at a depth of 5 cm. In women, organisms are recoverable at a depth of 2 cm. from most urethras. Normal urinary tracts have considerable resistance to infection, so that instruments may be used in them with relative impunity, and consequently catheterization of normal persons seldom causes infection. However, this may have less than major application to the problem, since manipulation is more likely to be carried out in persons who do not have a normal urinary tract. Little dispute appears regarding the increases in danger of postcatheterization infection by pre-existing disease of the urinary tract. Regardless of whether the catheter introduces infection, continued use of the instrument in selected situations is unavoidable. Such use has relieved many patients of painfully distended bladders and has saved some from uremic death. The problem is not whether the catheter should be used but rather how it can be used more efficiently. The implication is obvious, however, that adequate attention should be paid to the technic of catheterization and that the catheter should be used with discrimination.

Antibacterial-Induced Floral Changes

In general, antibacterial agents may be responsible for iatrogenic changes in the body flora, resulting in urinary infections; for example, penicillin and allied drugs, perhaps given for a respiratory infection, may depress the gram-positive elements, and the overgrowing gram-negative bacteria may invade the urinary tract. Conversely, drugs depressing the gram-negative flora, such as the tetracyclines, may allow overgrowth of gram-positive bacteria and consequently urinary invasion.

Predisposing Disease

Certain diseases, such as diabetes mellitus, predispose to infections of the urinary tract. Some diseases, such as hyperparathyroidism and lymphoma, may predispose to infection by inducing obstructive uropathy. Others, such as amyloidosis and glomerulonephritis, may be complicated by secondary infection. The sickling trait may result in vascular thrombosis and changes in the renal medulla which may enhance infection.

Metastatic Infection

Metastatic involvement of the kidneys, as exemplified by septic infarcts in bacteremia or endocarditis, is an obvious factor. There is the paradox that, conversely, septic emboli may arise from the kidney and produce metastatic abscesses elsewhere.[10] A furuncle or carbuncle that is present a few weeks before the onset of a perinephritic abscess is suggestive of a staphylococcal cause.

Miscellaneous

Nonspecific antibacterial substances have been described as being present in normal urine; their disappearance or the appearance of other substances encouraging bacterial growth in the urine are possible etiologic factors. The fourth component of complement is inactivated by ammonia, and the production of ammonia from glutamine by the renal medulla has been given in explanation of its special susceptibility to infection. However, the current concept is that low complement per se does not predispose to infection elsewhere in the body. Some evidence exists that the mucosal cells of the urinary bladder possess an antibacterial mechanism that may explain spontaneous subsidence of certain cases of cystitis.

Trauma to the kidneys, as may occur in participants in contact sports and in victims of auto accidents, with resulting scarring, theoretically could enhance future infection.

Some investigators mention increased functional demands on the kidneys as enhancing infections. By this is meant that the burdens of drug excretion, as with some of the barbiturates, or that the excretion of metabolites, as urea after violent exercise, may exhaust the organs' resistance to the point of increasing their susceptibility to infection.

Some data have been interpreted as indicating that hypokalemic nephropathy increases the patient's susceptibility to pyelonephritis.

Diabetic Nephropathy*

Diabetic "nephropathy" refers to the complex picture of arterial, arteriolar, glomerular and tubular lesions, pyelonephritis and papillary necrosis, which appear to be the inevitable consequence of long-continued diabetes.[1,2] From the time of Richard Bright it had been recognized that "nephritis" was very common in patients with diabetes, and renal tubular lesions had been described by Armanni as early as 1875. For many years these were regarded as the most valuable post-mortem evidence of diabetes. In 1936 Kimmelstiel and Wilson[3] observed and described in eight patients (seven of whom had diabetes) the unique nodular glomerulosclerotic lesion of "intercapillary" origin. Later Bell[4] and others[5] defined a "diffuse glomerulosclerosis" which was also attributed to the diabetic process. However, diffuse glomerulosclerosis was observed in other conditions and its exact relationship to nodular diabetic glomerulosclerosis remained obscure prior to electronmicroscopy. A third group of glomerular lesions, the "exudative lesions," were observed by light microscopy.[6,7] These lesions were also found in conditions other than diabetes.

"Kimmelstiel-Wilson disease or syndrome" is a misnomer arising from reference to the nephrotic syndrome and not the significant renal lesions. Diagnosing nodular glomerulosclerosis at the bedside should be avoided, and the term "Kimmelstiel-Wilson syndrome" might well be abandoned. Less than 10 percent of patients with nodular glomerulosclerosis also have the nephrotic syndrome. Diffuse glomerulosclerosis is closely associated with renal failure and proteinuria and its clinical features in diabetes.[1]

Histology, Pathogenesis, and Etiology

The lesions generally considered indicative of diabetes are: glycogen-filled epithelial cells in the straight distal portion of proximal convoluted tubules (Armanni-Ebstein cells) and nodular glomerulosclerosis.[2] Kark and Gellman have studied the diabetic kidney by renal biopsy during life and at autopsy. Kark prefers the term nodular glomerulosclerosis rather than

---

*Medical Grand Rounds, Mt. Sinai Hospital, March 10, 1964.

Continued

intercapillary glomerulosclerosis. Three types of glomerulosclerosis are recognized and described: nodular, diffuse, and exudative.

Nodular Glomerulosclerosis

Histologically this lesion is characterized by a unique nodular deposit at the periphery of the glomerular capillary tuft. The nodules appear laminated and are surrounded by one or more layers of crowded, somewhat pyknotic nuclei. In the early stages, dilated blood-filled capillaries surround the nodule. Reticulin fibers can be demonstrated in the nodules, which also contain muco-polysaccharide, lipid, and hemoglobin.[8] With light microscopy, during the earliest stage, the glomeruli are normal in size, and most of the capillaries retain normal thin basement membranes. The pertinent finding is the prominence of axial stalks due to slight widening, with deeply eosinophilic and PAS-positive deposits.[9] Occasionally there is an increase in nuclei of the mesangium. The basement membrane, as it reflects over the mesangium into the next capillary loop, is thickened two or three-fold and wrinkled. In this area there is deposition of PAS-positive filaments or fragments, which become coarse and coalesce to become small hyaline, homogenous deposits. At this stage, however, the changes are not sufficiently distinctive to warrant the designation of "nodule."

The most remarkable change by electronmicroscopy is seen in the mesangium, which widens with a conspicuously increased deposition of hyaline or basement membrane-like material not seen in normal kidneys or in diffuse-type glomerulosclerosis. Bowman's capsule is focally thickened and contains osmophilic, electron-dense, homogeneous material similar to that in the hilar vessels and preglomerular arterioles. In some areas this replaces smooth muscle cells. There is also an increase of collagen fibrils in the connective tissue surrounding the basement membrane of Bowman's capsule.

As the lesions progress, the deposit of hyaline material in the mesangium increases, and the masses become larger and coalesce. The basement membrane of many peripheral capillaries remains thin or only slightly thickened, but some areas become thickened three to five times. In these areas the epithelial foot processes become flattened and fixed, whereas the podocytes elsewhere are normal. In the advanced stage with fully developed nodules the peripheral capillaries become increasingly involved, with thickening of the basement membrane and narrowing of the lumen. There is also thickening of the tubular basement membrane and the hilar vessels. There are varying sized hyaline nodules of the basement membrane of hilar vessels protruding into their lumina.

Diffuse Glomerulosclerosis

In the earlier stage of diffuse glomerulosclerosis the basement membrane is characteristically thickened throughout the entire glomerulus and involves the peripheral portions of capillary loops. In later stages, the homogeneous basement membrane becomes much thicker, as much as ten times that of normal membrane, and is more wrinkled and folded. In addition, the basement membrane-like material in the mesangium increases greatly in amount and, together with the peripheral basement membrane, encroaches upon the capillary lumen which appears as a narrowed channel.

Exudative Glomerulosclerosis

This type is not so common or specific for diabetes as the above lesions. The long-standing hyperlipemia often present in diabetes may result in the development of fat globules in the tubules or in the glomeruli.[8] The tubular changes described in 1875 by Armanni-Ebstein as hyaline drops and vacuolation in the kidneys have now been shown to contain glycogen. Histochemically they stain as fibrinoid. The deposits have been shown to contain gamma globulin and frequently some lipid.[10] This type of change is not seen in renal biopsy specimens and is even infrequently seen at autopsy, since treatment of diabetes has improved.

In prediabetic adults, similar changes have been described by various authors. In a study performed on 11 diabetic and two prediabetic children, glomerular lesions were observed by electron microscopy even in the absence of renal dysfunction, hypertension, or retinopathy.[11] This nephropathy was focal within glomeruli and was characterized by accumulation of basement membrane-like material in mesangial areas, thickening of the basement membranes of capillaries, and electron-dense "deposits" randomly distributed in these regions. No relationship was demonstrable between nephropathy and the age of the patient, the duration of illness, the dosage of insulin, or the degree of diabetic control. The most significant change was a minimal increase of PAS-positive material in mesangial areas, which apparently represents the earliest manifestation of diabetic and prediabetic nephropathy detectable by light microscopy.

Two possible explanations are suggested by these findings. (1) The nodular form of diabetic glomerulosclerosis develops from the diffuse lesion by enlargement of hyaline deposits, which differ from each other only in the size and shape of the mass. (2) The specific nodule originates in the mesangium (previously referred to as intercapillary space) with secondary involvement of the peripheral basement membrane.

Most investigators agree that diffuse diabetic glomerulosclerosis is more common than the nodular type, but that the lesion is less specific. With light microscopy, the predominant deposition of "hyaline" material in the stalk is a distinguishing feature. The deposition of basement membrane-like material in the mesangium prior to the formation of a nodule is by itself not pathognomonic of diabetes but occurs to some extent in normal glomeruli and also in a variety of other pathologic conditions.[9]

Bell[4] has stated that the diffuse glomerular lesions are much more apt to produce renal failure than the nodular ones. Kark and associates[1] confirmed this opinion by means of renal biopsies in patients with long-standing diabetes and evidence of renal involvement. They found that the increase in severity of the diffuse lesion paralleled the clinical and laboratory signs of renal failure, such as albuminuria, edema, azotemia, decreased serum albumin, and decreased creatinine and urea clearances. There was no similar correlation between the severity of nodular lesions and the evidences of advance of renal failure.[3]

With the onset of proteinuria, the capillary wall through which the proteins must pass is widened by: (1) increase in amount of endothelial cytoplasm and disappearances of the pores, (2) the greater thickness of the basement membrane, (3) coalescence of epithelial foot processes so that the entire external surface of the capillary basement membrane is

Your patient doesn't have to be in the Masters to get sprains and strains

Regardless of the etiology of muscle sprain or strain, 'SOMA' COMPOUND helps relieve pain and relax muscle. Patient comfort can be increased and recovery time shortened.

Soma® Compound

carisoprodol 200 mg., acetophenetidin 160 mg., caffeine 32 mg.

rational combination therapy for sprains and strains: relaxes muscle, relieves pain. Also available with ¼ gr. codeine as 'SOMA' COMPOUND with CODEINE: carisoprodol 200 mg., acetophenetidin 160 mg., caffeine 32 mg., codeine phosphate 16 mg. (Warning: may be habit-forming.)

BRIEF SUMMARY
'SOMA' COMPOUND; 'SOMA' COMPOUND plus CODEINE: carisoprodol, acetophenetidin, caffeine, codeine phosphate. *Warning: Codeine may be habit-forming.* **Indications:** 'Soma' Compound and 'Soma' Compound with Codeine are indicated for relief of pain and stiffness in traumatic, rheumatic and other similar conditions. **Contraindications:** Allergic or idiosyncratic reactions to carisoprodol or codeine. **Precautions:** *Acetophenetidin*—May damage the kidneys when used in large amounts or for long periods. *Codeine*—Should be used with caution in addiction-prone individuals. *Carisoprodol*—Like other central nervous system depressants, should be used with caution in patients with known propensity for taking excessive quantities of drugs and in patients with known sensitivity to compounds of similar chemical structure, e.g., meprobamate. **Side effects:** *Codeine*—Nausea, vomiting, constipation, and miosis. *Carisoprodol*—The only side effect reported with any frequency is drowsiness, usually on higher than recommended doses. One instance each of pancytopenia and leukopenia occurring when carisoprodol was administered with other drugs has been reported as has an instance of fixed drug eruption with carisoprodol and subsequent cross-reaction to meprobamate. Rare allergic reactions, usually mild, have included one case each of anaphylactoid reaction with mild shock and angioneurotic edema with respiratory difficulty, both reversed with appropriate therapy. Other rarely observed reactions have included dizziness, ataxia, agitation, increase in eosinophil count, and gastrointestinal symptoms. Massive overdosage may produce coma and/or mild shock and respiratory depression. **Dosage:** 'Soma' Compound and 'Soma' Compound with Codeine, one or two tablets three times daily and at bedtime. **Supplied:** 'Soma' Compound, orange tablets, each containing carisoprodol 200 mg., acetophenetidin 160 mg., and caffeine 32 mg. 'Soma' Compound with Codeine, white, lozenge-shaped tablets, each containing carisoprodol 200 mg., acetophenetidin 160 mg., caffeine 32 mg., and codeine phosphate 16 mg. Narcotic order form required. *Before prescribing, consult package circular.*

WALLACE LABORATORIES
Cranbury, N. J.

CSO-3518

covered with epithelial cell cytoplasm.[10] In addition, both spithelial and endothelial cells show larger numbers of mitochondria and greater amounts of endoplasmic reticulum, changes usually associated with increased cellular work and synthesis of proteins. Finally, the surface of the epithelial cell exposed to Bowman's space is extended greatly by the formation of many more canaliculi.

Almost all patients with advanced glomerulosclerosis have hypertension and severe generalized arteriolar sclerosis involving both afferent and efferent arterioles of the glomerulus. Efferent arteriolar sclerosis, as emphasized by Bell, is specific for diabetes mellitus.[4] Ischemic obsolescence of the diabetic glomeruli is quite frequent, and this process often protects the glomerulus from formation of the nodules of diabetic glomerulosclerosis.[10]

Several interesting observations have suggested a possible etiology for the glomerulosclerosis. The staining characteristics and immunochemistry of the glomerular lesions suggest an immunologic mechanism.[12] These lesions were rarely observed in autopsies on diabetic patients who died before 1923, and who had not received insulin. In addition, fewer glomerular lesions have been reported in patients who had not received insulin. Insulin binding has been demonstrated in the lesions of the diabetic glomerulosclerotic kidney but not in the lesions of nondiabetic renal diseases such as chronic glomerulonephritis and malignant nephrosclerosis. Although these observations suggest that insulin, particularly exogenous insulin, may act as an antigen and participate in the formation of glomerulosclerosis, they do not explain the fact that early basement membrane changes can be seen coincident with the clinical onset of the disease. Submicroscopic basement membrane thickening may be an invariable part of diabetes, but microscopic or clinically evident glomerulosclerosis may be the result of antigenic activity plus other unknown factors.[13]

There is no incontrovertible evidence that the specific renal lesions of diabetes can be prevented by strict control of the disease. A lower incidence of all complications is found in patients who have been well controlled than in those who have been poorly controlled. Even in the well controlled group, however, incidence of complications is high in patients followed long enough.

Symptoms, Signs and Diagnosis

There are no specific symptoms of renal involvement in diabetes.[1] In known diabetics the urine should be examined frequently for evidence of renal damage. Persistent proteinuria, white cells or casts in the absence of infection suggest that the diffuse lesion is well established. The presence of oval fat bodies and fatty casts indicates the development of severe tubular changes. Unfortunately none of these urinary findings are pathognomonic of diabetic glomerulosclerosis. The only certain method of diagnosis ante mortem is by renal biopsy; however, suspicion should be aroused by the finding of proteinuria, hypertension, and azotemia. The presence of the nephrotic syndrome makes the diagnosis virtually certain. Kark and his co-workers have presented the most comprehensive account of the clinical correlations and renal functional changes associated with diabetic glomerulosclerosis. These findings are summarized in the following tables.

Continued

TABLE 1
Clinical Features in Diabetic Glomerulosclerosis*

	Type of Pathologic Change	
Clinical Features	Predominantly Diffuse	Predominantly Nodular
Sex	No correlation	Same
Age	More severe with younger age at onset	Same
Duration of diabetes	More severe with increased duration	Same
Incidence of hypertension	Positive correlation	No correlation
Type or duration of insulin therapy	No correlation	No correlation
History of diabetic ketosis	Positive correlation	No correlation
Retinopathy	Positive correlation	Positive correlation
Peripheral vascular disease	No correlation	No correlation
Edema	Positive correlation	No correlation
Nephrotic syndrome	Positive correlation	No correlation

Positive correlation: The presence or the frequency of the clinical feature is related to increasing severity of the specific pathologic change.

No correlation: Clinical features are independent of the pathologic change.

TABLE 2
Laboratory Findings in Diabetic Glomerulosclerosis*[9]

	Type of Pathologic Change	
Laboratory Findings	Predominantly Diffuse	Predominantly Nodular
Urine		
(1) Proteinuria	Positive correlation	± Correlation
(2) Sediment—WBC, RBC, Casts	Positive correlation	± Correlation
Blood Chemistry		
(1) BUN-NPH	Positive correlation	No correlation
(2) Creatinine	Positive correlation	No correlation
(3) Serum albumin	Positive correlation	No correlation
(4) Serum cholesterol	No correlation	No correlation
Renal Function		
Urea clearance	Positive correlation	No correlation
Creatinine clearance	Positive correlation	No correlation

Positive correlation: A greater degree of abnormality of the laboratory finding is usually associated with an increasingly severe pathologic change.

No correlation: No predictable relationship between the laboratory abnormality and the extent of the pathologic change.

*Lee, Charles T., Jr., M.D.: Renal Disease in Diabetes Mellitus. Med Clin N Amer 47:1076, 1963.

The lesions show no predilection for either sex. They are more frequent and severe in patients with the lowest age of onset and with increasing duration of diabetes. Hypertension and edema are more frequently attributed to congestive heart failure than to the nephrotic syndrome. Insulin therapy cannot be correlated with the degree of pathologic change. If one uses the frequency of diabetic ketosis as a rough guide to the adequacy of diabetic control, it appears that poor control may result in proportionately more severe diffuse changes. Retinopathy and glomerulosclerosis are almost invariably found together, and the severity of one mirrors the severity of the other. For practical purposes it appears that the best and easiest way to judge the amount of renal damage in a given patient is a careful funduscopic examination. Rather surprisingly, other evidence of vascular disease in the heart, brain, or extremities bears no direct relation to the specific pathologic entity of glomerulosclerosis. On the other hand, peripheral arteriosclerosis is associated with nephrosclerosis, proliferative arterial changes, and renal artery arteriosclerosis in diabetic patients.[13]

Occasionally patients, not previously known to have diabetes, present with renal failure and glycosuria and are subsequently found to have the glomerular lesions specific for diabetes. The development of renal disease in diabetes is sometimes associated with the reduction or disappearance of glycosuria,[1] the mechanism for which is not clear. Reduction of glomerular filtration might permit the tubules to reabsorb all the glucose that reaches them. There have been occasional cases reported in which the diabetes, as measured by glucose tolerance, seemed to undergo a complete remission.[14] One factor may be the decrease in caloric intake associated with the inactivity, anorexia, and nausea of renal failure. Since a proportion of the circulating insulin exists in the body bound to serum albumin as a metabolically inactive complex, hypoalbuminemia may lead to a greater amount of free, active insulin. Finally, the immune mechanisms which produce insulin antibodies and insulin resistance may be decreased by the renal failure, and more insulin may thus become available for metabolic activity.

Prevention and Treatment of Diabetic Glomerulosclerosis

There is a definite difference of opinion regarding the prevention of glomerulosclerosis. One group believes that clinical nephropathy is inevitable in every diabetic if he survives long enough. Another group points out that patients with the most severe diabetes and with the poorest control are the ones who generally develop rapidly progressive renal failure. The question then arises: if this is an inevitable part of the severe diabetic state, why is it that occasional patients who have had the juvenile type of the disease 25 years or more do not show clinical or laboratory evidence of glomerulosclerosis? Both groups are probably partly right, since submicroscopic basement membrane changes may be present in all diabetics, but the rapidity with which these changes advance may be partially dependent upon the care exercised by the patient and physician in the control of the disease. It would still appear to be a reasonable concept that proper control of diabetes may help reduce glomerulosclerosis in the sense of helping to arrest progression.

Treatment consists of two phases: (1) control of the diabetes, and (2) management of progressive renal failure. Patients may become increasingly sensitive to insulin as the renal disease progresses and therefore may need less and less insulin. Since the high renal threshold gives a false impression of improved control of hyperglycemia, more reliance must be placed on the blood sugar as the index of diabetic control.[13] Once severe renal involvement has occurred, the management is in general not different from that of other varieties of chronic renal failure. A high proportion of patients develop blindness in association with this type of renal failure. Edema becomes increasingly difficult to relieve. Some degree of congestive cardiac failure usually occurs. In the earlier stages a moderate protein intake is allowed if the urea nitrogen is stable. Diuretics are used together with a modest restriction of sodium to one gram or less daily, provided this does not produce an increase in azotemia. Aldosterone antagonists may be

Continued

tried as the edema becomes resistant. When the blood urea nitrogen is rising, the dietary protein is restricted to 30 grams a day or less. Pyelonephritis is treated with appropriate antibiotics.

Case Report

This 47-year-old white male was first admitted to Mt. Sinai Hospital on 2-5-63 because of dyspnea, leg edema, and a chronic left heel ulcer. Diabetes mellitus had been present for 22 years and treated with 25 units NPH insulin. The condition had not required insulin prior to 1945, at which time, following an episode of pneumonia, he took insulin for a three-month period. About eight months prior to this admission he had been put back on insulin. The symptoms resulting in this hospitalization had begun two weeks before admission.

Physical examination revealed a blood pressure of 120/80. The retinae contained small hemorrhages with whitish exudates. Bilateral pleural effusion was present, and there were moist rales at both lung bases. The heart was enlarged to percussion, and the liver was palpable three cm. below the right costal margin. There was atrophy of interossei muscles of both hands, and pretibial and ankle edema. There was a large yellowish ulcer with surrounding induration on the left heel. Neurological examination revealed hypoactive to absent deep tendon reflexes in the lower extremities. Sensation was reduced in both legs and vibration sense was impaired in the left leg.

Blood urea nitrogen was 50 mg.%, fasting blood sugar 273 mg.%, total serum protein 6 gm.%, albumin 2.8 gm., globulin 3.2 gm. Bromsulfalein test was normal. Sedimentation rate was 123 mm. in one hour and hemoglobin 9.6 gm.%. Urinalysis revealed specific gravity 1.008, 2+ albuminuria, trace of sugar, 40-50 RBC, 2-4 WBC, 30-40 hyaline casts, a few bacteria, and a few epithelial cells per hpf. An EKG showed changes compatible with myocardial ischemia.

The patient was treated for congestive heart failure, and the diabetes was controlled with 20 units of NPH insulin. Staphylococcus aureus coagulase positive was cultured from the left heel ulcer and it was treated with antibiotics. He also received vitamin B12 and Cyclospasmol.® A neurology consultant made a diagnosis of diabetic pseudotabes. Cerebrospinal fluid protein was 51 mg.%. His general condition improved, and the edema decreased. Cultures of the left heel ulceration became negative, and the ulcer was slowly healing by granulation at the time of discharge on March 2, 1963. He left the hospital on an 1800 calorie low salt diabetic diet, NPH insulin, 25 units daily, diuril 500 mgm. daily, digitoxin 0.1 mg. daily, Cyclospasmol® 200 mgm. four times daily, and vitamin B12 injections 1000 mcg. IM twice weekly. He had lost a total of 21½ pounds during his hospitalization.

He was followed in the outpatient clinic until 7-3-63 when he was admitted to the Surgical Service for skin grafting of the chronic ulcer on the left heel. Then because of increasing congestive heart failure, he was transferred to the Medical Service. He complained of sexual impotency for the first time. There were bilateral pleural effusions of a more severe degree than on the previous admission. Edema extended up to the sacrum with edema of the penis and scrotum. Femoral, popliteal, posterior tibial and dorsalis pedis pulses were all reduced. Laboratory studies at this time revealed hemoglobin 10.1 gm.%, 3+ albuminuria with 4-8 RBC and 1-3 WBC per hpf. Fasting blood sugar was 115 mg.%. Serum electrolytes were normal. Total serum protein was 5.8 gm.% with albumin 3.1 and globulin 3.7 gm.%. Blood sugars during this hospitalization fluctuated between 58 and 150 mg.%. Satisfactory diuresis was obtained with diamox and thiomerin in addition to Aldactizide, and there was a 24-pound weight loss by the time of discharge on July 16, 1963. The lower extremity edema had cleared almost completely. The ulcer on the left heel was treated with daily Dreft soaks and Panafil® ointment. He continued on Aldactizide, Digitoxin, and 20 units of NPH insulin, but Cyclospasmol was discontinued.

He was again admitted to the hospital on November 11, 1963, because of persistent ankle edema and weight gain. NPH insulin dosage had been progressively decreased because of recurrent hypoglycemia, so that his daily insulin dose on admission was only five units. There had been persistent nausea and intermittent vomiting for three months. Blood pressure was 148/90 and weight 174 pounds. There was advanced bilateral diabetic retinopathy with venous aneurysms, new vessel growth, and a large hemorrhage in the left retina. There was also marked bilateral pleural effusion and pulmonary congestion. The liver was palpable four cm. below the costal margin, and edema of the legs, the presacral area, and the penis and scrotum was marked. The ulceration of the left heel was partially healed. Hemoglobin was 9.3 gm.% There was 4+ albuminuria, specific gravity 1.015, 20-30 RBC, and 4-6 hyaline casts per hpf.

Blood urea nitrogen was 44 mg.%, and fasting blood sugar 120 mg.%. Total serum proteins were 5.4 gm.%, albumin 2.9, globulin 2.5 gm.%. Cholesterol was 167 mg.% and serum iron 41. He was treated with five units of NPH insulin daily and a strict low-salt diet. Thiomerin was used for diuresis. He was given two courses of Mannitol infusion with good diuresis after approximately 36 hours. His nausea cleared and his weight stabilized at 167 pounds.

On January 2, 1964 he was readmitted with a chief complaint of diarrhea. His blood pressure was 160/100. The fundi showed severe diabetic retinopathy with extensive hemorrhages, exudates, and microaneurysms, more marked on the right. There was massive bilateral pleural effusion. The liver was four cm. below the right costal margin and there was moderate ascites. Edema was marked, including the presacral area and the genitalia. The ulcer on the left heel was still not completely healed. Blood urea nitrogen was 79 mg.%, creatinine 3 mg.%, calcium 8.4 mg.%, phosphorous 5.8 mg.%, and fasting blood sugar 160 mg.%. Specific gravity of the urine was 1.010, albumin 2+, and glucose negative. Hemoglobin was 10.3 gm.%. He was placed on a 2,000 calorie diabetic diet and antispasmodics were used to control the diarrhea. NPH insulin was discontinued and Orinase 0.5 gm. daily started. He was also given periodic thiomerin injections. By the time of discharge the diarrhea had cleared, and the edema had subsided. A blood urea nitrogen before discharge was 40 mg.%, creatinine 2.6 mg.%, and blood glucose 110 mg.%. He was followed in the Outpatient Clinic until 3-6-64 when he was readmitted to the hospital because of intractable edema and dyspnea. During this admission he responded poorly to diuretic and cardiac management and required two thoracenteses to relieve dyspnea. Still edematous he was discharged at his request and died suddenly on 3-25-64 while at home. Permission for autopsy was not granted.

Abstracts, Briefs and Commentaries

POSTOPERATIVE WOUND INFECTIONS

A 192-page report has been submitted on a co-operative study by five academic institutions over a two-year period in an attempt to fully evaluate the influence of ultraviolet irradiation in the operating room on the incidence of postoperative wound infection.

The irradiation reduced the number of airborne bacteria in the operating room, but the wound infection rate was unchanged. Significant improvement did occur from 3.8 to 2.9 per cent infection rate in the refined-clean group. However, this was offset by an apparent detrimental effect in the nonclean wounds.

Secondary information was gathered in other aspects of the postoperative infection problem. It was found that diabetic patients showed no increased susceptibility to infection when compared to nondiabetics of similar ages. Steroid therapy appears to affect wound infection rates adversely. Extremely obese patients appear to be more susceptible to wound infection. Little evidence was found that a malnourished patient is more susceptible to infection. Patients who harbor infection remote from the operative incision are likely to have a greater wound infection rate. The duration of operation brings an increase of wound infection rate — the longer the operation, the more likely wound infection will appear. Thus duration appears to be the primary determinant of risk of infection.

The duration of preoperative hospitalization appears to influence the infection rate independently. The use of prophylactic antibiotics was associated with a much higher wound infection rate. However, the authors qualify this observation by the notation that obvious case selection may well be of significance, and state that only further carefully controlled studies can settle this issue of prophylactic antibiotics by a thoroughly randomized study.

The Influence of Ultraviolet Irradiation of the Operating Room and Various Other Factors. Supp to Ann Surg 160:August, 1964.

TREATMENT OF INFECTIOUS MONONUCLEOSIS

Since 1958 reports of dramatic response of infectious mononucleosis patients to chloroquine have appeared, but controlled studies apparently have not been made. This paper reports a double-blind study of 40 patients, half of whom were given chloroquine and the other 20 a placebo. Based on results, the authors conclude that the drug is beneficial in that it appears to shorten the course of the disease. The results, however, do not appear to confirm earlier reports of consistent dramatic responses to chloroquine, nor do they suggest that it would be reliable as a diagnostic test. Here are the comparative average durations in days for the 20 patients on chloroquine and the 20 on the placebo: (a) Hospitalization: placebo, 14; treated, 8.7; (b) Pharyngitis: placebo, 7.1; treated, 4.6; (c) Subjective Symptoms: placebo, 8.3; treated, 5; (d) Hepatomegaly: placebo, 11.8; treated, 6; (e) Fever: placebo, 7.1; treated, 5.3; (f) Liver Function Abnormalities: placebo, 10.5; treated, 9.2; (g) Splenomegaly or Lymphadenopathy: placebo, 9.6; treated, 7.1.

The patients were males ranging in age from seventeen to twenty-five (average 20.5 years) admitted to an army hospital over a six-month period. All of them fulfilled criteria for a conclusive diagnosis of infectious mononucleosis: absolute lymphocytosis with atypical lymphocytes; significant lymphadenopathy, fever, pharyngitis, and a changing heterophile antibody titer reaching a peak of 1:224 or greater. Placebo and active tablets were identical in appearance, with the number on the treatment box the only key to the identity of the agent received from the pharmacy. Patients were not aware that any study was being made. Which patients were chloroquine-treated or which received the placebo was not known until after final outpatient evaluation had been completed. Chloroquine dosage was 1 gram immediately; 0.5 gram in eight hours; 0.5 gram daily for nine days; and 0.025 gram daily for eight more days. At first patients were put on bed rest. Bathroom privileges were limited. Ambulation was permitted when temperatures became normal and spleen size was regressing. They were discharged to duty three to four days after the final temperature elevation. The authors describe laboratory procedures, not reviewed here. A daily check list on each patient was kept on a work sheet. Items were: general condition, throat condition, lymphadenopathy, spleen size, liver size, skin eruption, per cent of diet eaten, and any signs of drug reaction. Temperature and pulse were recorded every eight hours.

The authors discuss findings at some length. In answer to the question of whether all infectious mononucleosis patients should be given chloroquine the authors note that the study was too small to supply a definitive answer. They add, however, the following favorable points: (a) the cost of chloroquine is low; (b) if morbidity is reduced by only 20 per cent the saving in man hours would be worth while; and (c) chloroquine appears relatively safe for short-term use. In this series no serious side effects were noted.

Medical Abstract Service

LUMBAR SYMPATHECTOMY

The effect of lumbar sympathectomy upon blood flow to the skin and muscles of the lower extremities in eight patients with arteriosclerosis obliterans was measured plethysmographically. Twelve limbs were so measured. Six unilateral sympathectomies were performed and the post-sympathectomy data was available. The nonsympathectomized contralateral extremity was studied in three patients. Patients were studied by aortography and all demonstrated arteriosclerosis obliterans in the iliofemoral popliteal system not amenable to direct arterial reconstruction or graft. Patients with gangrene, loss of tissue, or ulcerations were not included. The lumbar sympathectomy consisted of removal of the sympathetic chain L1 through L4.

A constant environmental laboratory was kept standard in all experiments. Blood flow in the skin and muscle were tested under various physiologic dilator stimuli and drug vasodilator stimuli. The responses of the unoperated limb did not appear to be affected in any of the parameters measured.

It was the authors' conclusion that the early effects, 2-4 weeks postoperatively, of lumbar sympathectomy upon blood flow to the lower extremity appeared undesirable except for an increase in perfusion of the resting skin. There did not appear to be any "borrowing-lending" phenomena from one extremity to the other. Blood flow responses in the unoperated extremity were not altered by the sympathectomy on the contralateral side.

GUILLAIN-BARRE SYNDROME

The world literature on corticotropin and glucocorticoid therapy of the Guillain-Barre syndrome is reviewed pointing out that differences and discrepancies in diagnostic criteria, methods of therapy, and modes of reporting make the results difficult to evaluate. Eighteen patients treated with these hormones at the University of Michigan Medical Center are presented and compared with 17 nontreated patients who, however, did not constitute a true control group. The patients in both groups survived, but there was a suggestively favorable response in most of those receiving hormone therapy. Some of the difficulties in evaluating the results of this treatment are discussed. Further hormonal therapy in this condition seems justified, not only to give patients the benefit of the therapeutic response thus far demonstrated, but also to clarify the effect of such treatment and its relationship to the etiology and pathogenesis of the syndrome.

PERITONEAL DIALYSIS IN SALICYLATE POISONING

Four cases of salicylate intoxication were treated by continuous peritoneal dialysis. Observations showing the extensive depletion of available body base, especially potassium are reported. The clinical states appear to parallel these, rather than the serum salicylate levels. During dialysis the major repair process is correction of electrolyte depletions, which permits the effective renal excretion of salicylate. The various therapeutic measures available for treating salicylate intoxication are reviewed. Peritoneal dialysis is the simplest and most freely available of these. It is suggested on the basis of this experience that prevention

Continued

of salicylate intoxication now depends largely on accuracy of information in manufacturers' advertising.

LEAD EXPOSURE IN PAINTERS

Single blood lead concentration determinations were done among 107 male decorative and house painters employed by the Federal General Services Administration in the Washington, D.C. area. No elevated blood lead levels were found, the mean for the group being 0.023 mg. of lead per 100 gm. of whole blood, and the range from 0.013 to 0.040. This mean level approximated that of a control group of five males and the recently reported mean blood concentration value of an urban male population. The federal painters' practices are thought to be representative, and their risk of lead poisoning associated with current materials and methods of application used in the decorative and house painting trades appears to be negligible. Within the painter group, no significant relationship between blood lead values were associated with age, methods of application, or number of years engaged in the painting trades.

ANAL FISTULAS

There are two groups of anal fisulas: 5 percent are complex and difficult to deal with, while 95 percent are simple and easily cured.

There is no difficulty in distinguishing a simple from a complex fistula. The track of a simple fistula can be palpated as a thick, fibrous cord running from the external opening towards the anal canal. A probe passed through the track lies transversely to the axis of the rectum.

In the complex fistula no track can be palpated subcutaneously and the probe passes upward parallel to the axis of the rectum for six to seven cm. to the apex of the ischiorectal fossa. On rectal examination a horseshoe induration is felt just below the level of the anal ring.

The orthodox treatment is to lay open the whole track, so as to convert it into a racket-shaped wound. If this were done in a simple fistula, on a desert island, with no other treatment except a morning and evening swim in the sea, the fistula would heal. The complex fistula is a different matter.

To lay open a horseshoe fistula requires an incision in the perianal skin involving almost the entire circumference of the anus. To flatten the wound adequately requires the sacrifice of a large amount of skin and the resulting wound may take eight to ten weeks to heal.

The fistula whose internal opening lies above the anorectal ring cannot be treated by the classical method without producing incontinence. Fear of dividing too much of the sphincter muscle and rendering the patient incontinent is often responsible for the inadequate treatment.

With a knowledge of the etiology and the relation to the sphincter muscles, healing of a simple fistula by orthodox methods presents no problems. Complex fistulas may tax the patient's endurance and the surgeon's skill to the utmost.

KVEIM TEST FOR SARCOIDOSIS

A "double-blind" study of the Kveim test was undertaken in a test-series of patients with active and inactive sarcoidosis on and off steroid therapy, and in a contratest series that included patients with active tuberculosis and normal subjects with negative tuberculin reactions. This study led to the following conclusions: (1) When properly performed with antigen prepared from sarcoid tissue, the Kveim test is a specific diagnostic tool for detection of patients with active sarcoid. (2) Patients with inactive sarcoid may give positive or negative reactions, but patients who do not have sarcoid do not have a positive Kveim reaction when injected with a good sarcoid antigen. (3) Steroid therapy in active sarcoidosis does not prevent a positive Kveim reaction. (4) Antigen prepared from normal tissue may give reactions resembling "foreign body giant cell granuloma" only in patients with active sarcoid, suggesting a special hypersensitivity to foreign tissue rather than antigen-antibody relationship. (5) There is no necessity to perform a biopsy in a patient who has not developed a macroscopic lesion, but histopathological examination of gross lesions is always necessary.

OTITIS EXTERNA

Virtually all manifestations of otitis externa are controllable by the administration of an acid alcohol, or acid alcohol-hydrocortisone, solution. This result, however, is accomplished only after thorough cleaning of the external canal. Cleaning is done painlessly with a proteolytic enzyme ointment as a debriding agent. Therapy is begun only after the external canal is clean. Complete remission of symptoms was obtained in an average of 4.4 days, without any evidence of sensitization to the preparations used.

Jenkins, B.: Arch Otolaryng 77:442, 1963

DIRECT VISION ADENOIDECTOMY

One item in any program to prevent hearing loss is safeguarding the eustachian tube during adenotonsillectomy. Since this procedure is the most frequently performed operation in the United States, precautions assume particular importance. The best way of doing this, says the author, is to rely on direct preoperative inspection, direct observation during surgery, meticulous surgical technic, and postoperative inspection and follow-up. Removal of adenoid tissue under direct vision or with the help of a large pharyngeal mirror is better than relying on blind procedures done by sense of touch, which may result in leaving adenoid tissue remnants or danger to the eustachian tube. Damage to this orifice during adenoid surgery is not too uncommon, causing persistent serous otitis media which may lead to adhesive otitis media. Of 500 consecutive cases having adenoid and/or tonsil operations, 53 (10.6 percent) were revision adenoidectomies. Only one of these latter had been originally operated on by direct vision. Every one of the revisions (100 per cent) had transient or permanent hearing loss as the chief complaint. Chronic otitis media was present in 21.1 percent; onset was after the first operation. While frank stenosis and evidence of eustachian tube injury was present in 9.6

Continued

percent, none of these had chronic middle ear infection, but all showed signs of persistent or recurrent serous otitis media.

Even in children too young to be co-operative, preoperative evaluation is possible after shrinkage of the nasal membranes by anterior rhinoscopy. Most opportune is the time before surgery when the child is fully anesthetized. The lower two-thirds of the nasopharynx can be exposed by means of using the various models of palate restractors, the hooked end of a Davis tongue blade, or 2 rubber catheters introduced through the nostrils and grasped in the pharynx. The upper third can be inspected with a large pharyngeal mirror dipped in any soapy solution to prevent fogging. For the vault, palpation with the finger is unsatisfactory except for the lateral nasopharyngeal wall with the tube orifices.

A preferred method is use of both a square and a narrow, long curette, the latter serving as a palate elevator which, with the laryngeal mirror in place, can be positioned properly to remove with one stroke the total amount of central adenoid tissue. Firm contact is obtained with the superior edge of the posterior septum. With the left thumb as a fulcrum, the curette is guided inferiorly, keeping contact until the superior border of the superior constrictor muscle is approached, when the contact pressure is released. Use of a sharp cutting edge minimizes danger of tearing the superior constrictor muscle. Now a long narrow curette is introduced into the superior recess of the right fossa of Rosenmuller. Here care is taken not to engage the tubal orifice; this is done by tilting the curette handle to the right. This is repeated on the left side. Postoperatively, the nasopharynx is inspected again. Bleeding having stopped by this time, remnants of lymph tissue will be revealed by aspiration of blood clots. This also will prevent aspiration of clots from the nose later. Bits of lymph tissue may be easily removed by triangular biopsy forceps.

RUNAWAY CHILDREN

Self-estimates of children in regard to their degree of control over external events (dimension of outer control to uncontrol) were measured on the basis of ratings of clinical interview data. Forty-two runaways, of both sexes, with a median age of 13.5 years, were compared with a similar group of non-runaway disturbed children. The runaways were rated as experiencing significantly more outer uncontrol on three relevant scales. The interpretation is that, on a gradient of generalized control-uncontrol, the more experience there is of losing control, the more likely it is that extreme behavior, such as running away from home, will eventuate.

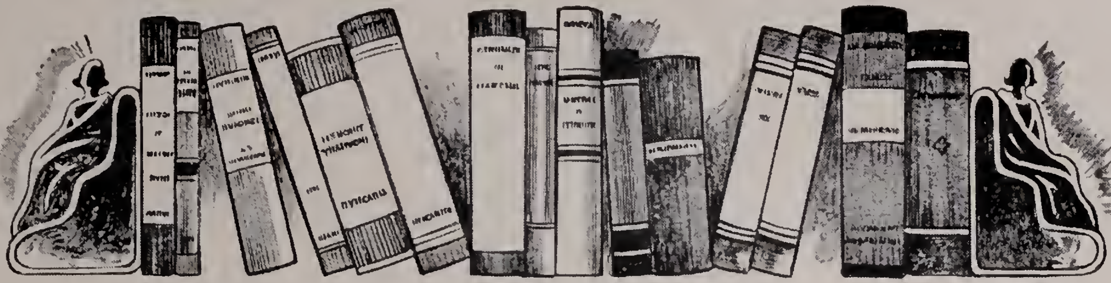
Leventhal, T.: Arch Gen Psychiat 9:122, 1963

The great question which, in all ages, has disturbed mankind, and brought on them the greatest part of those mischiefs which have ruined cities, depopulated countries, and disordered the peace of the world, has been, not whether there be power in the world, not whence it came, but who should have it.—John Locke

Inflation is repudiation.—Calvin Coolidge



Book Reviews

I love to lose myself in other men's minds. When I am not walking, I am reading. I cannot sit and think; books think for me.—Charles Lamb

MODERN TREATMENT — **Vol. 1, Nos. 2, 3, and 4, March, May, and July, 1964. By various authors. Harper and Row, New York. A Bimonthly publication, $16.00/year.**

The plan of this new series of books apparently is to assign a subject to a guest editor and to publish bimonthly under the general heading "Modern Treatment." The three books considered here take up lung and liver disease in the February issue; anemias and cardiac arrhythmias in May; and infectious diseases in July. "Treatment" is a magic word in medical publications attracting readers who might not respond to such a title word as "diagnosis." The problem is nicely put by Edwin Bayrd: "Consider the 55 year old tired housewife, whose anemia responds gratifyingly to iron, who finds a year later that her silent cecal carcinoma has now metastasized. Less tragic is the 60 year old farm wife who has received weekly injections of liver and 16,425 pills over a period of 15 years without any improvement in her anemia or myxedema." The greatest drawback of this series is that several of the authors have taken their therapeutic assignments literally, neglecting discussion of other aspects upon which treatment is based. The day has not passed, Bayrd to the contrary, that diagnosis before therapy needs be stressed. With this reservation the reviewer learned much about therapy from these volumes. Forthcoming subjects in this series will include headache, menstrual disorders, arthritis, epilepsy, acid peptic disease. All of these subjects should be interesting to the medical profession. The editing leaves something to be desired. Forgiveable is the parenthetic (32.9° F.) to explain the 0.5° C. which is the greatest allowable difference between mouth and rectal temperatures. Sixteen blank pages which crop up two at a time in the copy of "Infectious Diseases" are downright irritating.

Reuben Berman, M.D.
Minneapolis, Minnesota

BETTER HEALTH FOR WOMEN — **Charles Richard Alsop Gilbert, M.D., Doubleday & Co., 1964, $4.95 365 pages**

This book is written principally for the woman patient. It deals fully with functional, organic, and physiologic phases from the beginning of puberty to the adult life.

Each chapter contains a series of questions and answers. The nine or ten illustrations in the book seem to be adequate, as in a book of this nature there is no need of extensive anatomical drawings or technical procedures.

This book would be superfluous for the physician and is essentially for the woman patient. Doctors could well afford to give this book to their apprehensive gynecologic patients.

Carl O. Rice, M.D.
Minneapolis, Minnesota

EARLY TREATMENT OF FACIAL INJURIES — **Thomas John Zaydon, James Barrett Brown, Leo & Febiger 1964, No price listed**

This is a short, concise, but detailed monograph on facial injuries, excluding the eye, that should appeal to any physician who cares for patients with acute trauma. Although certain of the techniques of reduction of the facial bones after fracture will not be applicable to other than a specialist in that field, the knowledge to be gained by reading those chapters should be of great help to all physicians treating the less extensive facial injury.

The chapter on soft tissue wound care is a model of clarity, yet obviously represents the authors' tremendous experience in plastic surgery. This in an excellent book and should prove to be quite popular.

Perinatal Mortality Study

Characteristic Facies Associated with Bilateral Renal Agenesis

Case Report

The 20-year-old mother of this infant was Rh positive and this was her first pregnancy. She had no illness or drugs during the pregnancy, and at 7½ months spontaneously went into labor and had a double footling delivery of a male infant weighing 3 pounds, 12 ounces. No anesthetics were used during the delivery.

The infant was cyanotic and gasping. The ears were low-set, "floppy," folded and malformed. There was a wide epicanthal fold bilaterally which extended out over the malar bones. Periorbital edema was present. The jaw appeared to recede, giving the face a "pinched" appearance. Rales were heard throughout all lung fields. The liver was palpable 2 cm. below the right costal margin. There was an equinovarus deformity of the left foot. In spite of positive pressure oxygen therapy, the respirations diminished and the child died 2 hours, 45 minutes following birth.

Autopsy on the infant revealed both kidneys and ureters to be absent. The urachus was present and ended in a string-like urinary bladder. The urethra was patent. The testes were intra-abdominal. The adrenals together weighed 6.8 grams and were flat, hyperemic, closely apposed to the psoas muscle bilaterally. The lungs were normal in configuration but small in size. They were not weighed apart from the heart which was normal. The heart and lungs together weighed 35.5 grams. Microscopic sections of the lungs showed severe atelectasis. The remainder of the organs were normal for a premature infant.

Comment

Potter[1] describes characteristic facies associated with bilateral renal agenesis, enabling the condition to be diagnosed at birth. She states, "The facial expression is generally that of extreme age and is characteristic enough to warrant a diagnosis of renal agenesis from inspection of the face alone. This appearance seems to be related to lack of kidney function rather than to the specific malformation because a somewhat similar appearance is found in some infants with fatal polycystic changes or extreme renal hypoplasia.

"The most constant facial characteristic is a very prominent epicanthic fold that forms a semicircle arising on the forehead, swinging down to cover the medial palpebral commissure and ending on the cheek. It is different from the fold in mongolism, which ordinarily ends at the level of the commissure. The nose is usually flattened, the depression below the lower lip is unusually prominent and the ears ordinarily contain little cartilage, are flat without a formed helix and often are set at an angle exceptionally low on the sides of the head.

"Intrauterine life does not appear to be hampered by absence of kidneys, for many of these infants are born normally at term. Because waste products are successfully eliminated via the placenta, urinary secretion is not necessary to maintain intrauterine life. The longest survival in our series was 11 hours. Death of all the live-born infants was preceded by dyspnea, cyanosis and evidence of respiratory embarrassment. The lungs of all were hypoplastic, and this pulmonary abnormality was fatal before the absence of the kidneys could cause death from uremia."

Schaffer[2] verifies Potter's description of the facies associated with bilateral renal agenesis and states that almost all the subjects are male.

Continued

Ramsey County Perinatal Mortality Study Committee.

Summary

A case of bilateral renal agenesis associated with characteristic facies as described by Potter[1] is presented. The presence of bilateral wide epicanthic folds extending out over the malar bones with low-set, "floppy," malformed ears should alert the physician to the correct diagnosis and ultimate prognosis in these infants.

The Ramsey County Perinatal Study Committee strongly encourages autopsies in all perinatal deaths. In this way, important information may be gained from these fetal and neonatal deaths.

Three M's in the Renaissance

Medicine's progress in the Renaissance was distinguished for its resolute and heroic effort to repudiate its heritage of superstition and magic by identifying itself with the current scientific advances of the period. Chemistry and biology were still in their infancy; only mathematics and mechanics had attained a reputably mature status. So medicine, eager to turn its back on past errors and follies, attempted to synthesize its principles with those of mathematics and mechanics.

"The experimenters began to weigh and measure the various parts of man, as if he were so much brick, cement and lead piping. So it was reckoned that the muscles moving the thumb weighed 122 grains and they were estimated to develop a power of 3,270 pounds; accordingly the stomach, although weighing only eight ounces, could generate a force of 117,088 pounds, increasing to 461,219 pounds when the muscles of the abdomen and diaphragm were working full strength. Fruitless efforts were made to calculate the weight of an individual spermatozoon. The most logical absurdity, however, that arose from the school of 'physical' medicine, was the mathematical theory which worked out the span of life depending on the number of times a man's heart had been geared to beat. So that if a person had a heart fixed to last seventy years provided it beat at an average rate of sixty times a minute, then too much excitement which raised the heart beats to an average of seventy-five a minute would automatically determine the man's end at fifty-six years."*

However implausible the results of medicine's synthesis with mathematics and mechanics, they were historically significant in marking medicine's emergence into the light of rational thinking and scientific practice.

Rheumatic Fever

Minnesota Secondary Prevention Program Part II—Recurrences[*]

LAWRENCE V. PERLMAN, M.D.[**]
DEAN S. FLEMING, M.D.[***]
THOMAS J. THOM[†]
Minneapolis, Minnesota

THE PURPOSE of the Minnesota Rheumatic Fever Secondary Prevention Program is the prevention of recurrent rheumatic fever by professional education, the maintenance of a medical registry, and the provision of low cost prophylaxis. This program was designed as a service project and not as a research program, because the effectiveness of prophylactic sulfadiazine and penicillin has been demonstrated in many studies.[1,2] However, in order to assess the effectiveness of this particular program, the Minnesota Department of Health, in consultation with the Rheumatic Fever Committee of the Minnesota Heart Association and the Heart Committee of the Minnesota State Medical Association, has been collecting data on reported recurrences of rheumatic fever and streptococcal infections.

The purpose of this report is to record and comment upon these recurrences for the first four years of operation of the program — January 27, 1960 to January 27, 1964 — among the first 8,604 patients registered.

Mode of Operation

A recurrence of rheumatic fever or a streptococcal infection may be reported in one of two ways. First, attached to each book of prescriptions mailed to the physician for patient use is a post card by which the physician may notify the Heart Disease Control Program of the Minnesota Department of Health of an episode of acute rheumatic fever (Figure 1). Second, every twelve months the physician is sent a reapplication form on which he indicates whether or not the patient has had a recurrence of rheumatic fever or a streptococcal infection (Figure 2). The majority of recurrences are noted in the latter manner. If there is indication by one of these means that a recurrence or a streptococcal breakthrough has occurred, a second form (Figure 3) is sent to the physician asking him to describe the episode in detail.

DOCTOR: PLEASE NOTE

We are most anxious to be informed of recurrences of rheumatic fever as soon as they occur so that we can better evaluate the effectiveness of the prophylactic regimen presently being provided under this program.

Please use this postal card to notify us at once if your patient should have a recurrence.

NOTICE

You will AUTOMATICALLY receive a re-application for additional prescriptions for this patient when all four prescriptions have been filled. If it is necessary for you to write for additional prescriptions or any other reason, PLEASE USE YOUR STATIONERY WITH LETTERHEAD.

PSYCHIATRY FOR THE MEDICAL PRACTITIONER

New Orleans, Louisiana March 4-6, 1965

Sponsored by the DIVISION OF NEUROLOGY AND PSYCHIATRY OF TOURO INFIRMARY
under a National Institute of Mental Health Grant

GUEST LECTURERS INCLUDE:

Jack Ewalt, M.D., Prof. of Psychiatry, Harvard Med. School, Past Pres. of American Psychiatric Association, Boston, Mass.

John Lambert, M.D., Medical Director, Four Winds Hospital, Katonah, N. Y.

Zigmond Lebensohn, M.D., Chief, Dept. of Psychiatry, Sibley Memorial Hospital, Washington, D. C.

William Sheeley, M.D., Director of Psychiatry & Medical Practice Project of the A.P.A., Washington, D. C.

Philip Solomon, M.D., Chairman, A.P.A. Committee on Medical Practice, Boston, Mass.

Course will be given at Jung Hotel, 1500 Canal Street, New Orleans, La. Hotel reservations to be made directly with the Jung or hotel of your choice. Registrants who would like to enjoy Mardi Gras (March 2) are urged to make hotel reservations *immediately.*

Guest speaker for the luncheon on March 4 will be GEORGE BURCH, M.D., Henderson Professor and Chairman, Dept. of Medicine, Tulane Medical School. Subject: *"Emotions and Cardiovascular Disease."* Cost of luncheon included in registration fee. At the end of Friday's session, there will be a dutch treat two-hour cocktail party with George Lewis and his band from Preservation Hall entertaining.

AMONG TOPICS TO BE DISCUSSED:

"Detection of Incipient Psychiatric Disorders During a General Medical Examination"
"Medical Practitioners and Supportive Handling of Schizophrenia"
"Adolescents — Disturbed and Disturbing"
"The Physician and His Reaction to the 'Crock' "
"Newer Thoughts About the Therapy of Alcoholism"
"Medical Conditions with Psychiatric Manifestations"
"Recognition and Treatment of Depressive Reactions by Medical Practitioners"
"Treatment of Emotional States by the Medical Practitioner"

Gene L. Usdin, M.D., Chief
Division of Neurology & Psychiatry
Touro Infirmary
3516 Prytania Street
New Orleans, La. 70115

Enclosed is my registration fee of $20 for the *"Psychiatry for the Medical Practitioner"* course to be given March 4-6, 1965, at the Jung Hotel. (Checks should be made payable to Touro Infirmary.)

Results

In the first four years of the program, 235 recurrences of rheumatic fever and 262 episodes of acute streptococcal infections were reported. Detailed information was obtained through a follow-up questionnaire (Figure 3) on 81.7 per cent (192) of the recurrent episodes and 86.6 per cent (227) of the streptococcal infections.

Table 1 summarizes the results of the 192 recurrences on which detailed information was returned. Considering only these 192, 63.2 per cent (120) met Jones Criteria. In 2.6 per cent (5) of the cases, chorea was the only major manifestation cited. The 72 cases where Jones Criteria is questionable include 28 cases where sufficient minor criteria were present but the physician was uncertain about the presence of the major criteria. In these cases the usual source of confusion was the distinction between subjective complaints of arthralgia and objective manifestations of polyarthritis. In another 44 cases minor criteria were present, but no major criteria were even suspected. These were most often patients with a past history of rheumatic fever who had vague symptomatology and low grade fever (99°-100°). More often than not these patients had no rheumatic heart disease.

The gross recurrence rate for the first four years of operation of the secondary prevention program was 1.44 recurrences per hundred years. Assuming that 63.2 per cent of all recurrences reported met Jones Criteria and allowing for a 20 per cent rate of case closure, the adjusted recurrence rate is .93 recurrences per hundred patient years.* This is comparable to the rates in both the Chicago (1.0 per 100 patient years) and the Iowa (1.3 per 100 patient years) prophylaxis programs.[3,4]

Two hundred sixty-two streptococcal infections (defined in various ways by different clinicians, but usually based on the presence of pharyngitis) were reported for an incidence of 1.61 infections per 100 patient years. Of these, 43 per cent (115) were followed by acute rheumatic fever (Table 2). Considering these 115 cases of clinical streptococcal infection followed by rheumatic disease, 17.4 per cent (20) had cultures taken (14 were positive and 6 negative). However, 30.7 per cent (45) of those 147 without rheumatic sequelae were cultured and of these 39 were positive and 6 negative.

Discussion

The fulfillment of Jones Criteria is probably the minimum requirement for a diagnosis of rheumatic fever.[5] However, there are any number of diseases which may fulfill Jones Criteria (Table 3) and still not be acute rheumatic disease. The clinical and public health significance of rheumatic fever is that it is causally related to streptococcal infection and followed in a variable number of instances by heart disease.

The occurrence of vague complaints referrable to the musculo-skeletal system and often accompanied by elevated sedimentation rates, slight leucocytosis, and low grade fever in individuals with a past history of rheumatic fever is provocative but of questionable significance. Many qualified observers feel that these illnesses are not followed by cardiac damage and if causally related to streptococcal infections should be called poststreptococcal arthralgia and not rheumatic fever.[6,7] From 20 to 40 per cent of the recurrences reported to this program fall into this category.

Expected recurrence rates among rheumatic individuals without the benefit of prophylaxis vary with age, length of time of freedom from rheumatic activity, and socioeconomic conditions. Rates vary between six and forty per 100 patient years.[8,9] The observed recurrence rate in this program is much less than these figures and it agrees with that observed in other prophylactic programs.

Two hundred sixty-two streptococcal infections were reported as of January, 1964, and of these 43.9 per cent (115) were fol-

Continued

---

*The true recurrence rate lies between .93 per 100 patient years and 1.44 per 100 patient years. A certain number of individuals enrolled probably do not have rheumatic fever and therefore one has to assume that there is a constant, but not necessarily equal, observer error in diagnosing both initial and recurrent cases of rheumatic fever.

lowed by rheumatic fever. This probably represents an under-reporting of streptococcal infections which can be explained by the fact that less than half of streptococcal infections present the classic combination of fever and exudative tonsillitis. Streptococcal infections may be totally asymptomatic or manifest themselves as upper respiratory infections, nonexudative tonsillitis or brief fevers of unknown origin.[10] This underscores the necessity for continual rather than interrupted prophylaxis.

It is significant ($p > .02$) that almost twice as many throat cultures were taken in individuals with clinical streptococcal infections without subsequent rheumatic fever as opposed to those whose illnesses were followed by recurrent rheumatic disease. The purpose of doing throat cultures in individuals with increased rheumatic susceptibility is aimed at identifying the streptococcus. Eradication of streptococcal infection requires ten days of bactericidal therapy.[11] Since this is difficult and somewhat costly, the knowledge that one is dealing with the beta hemolytic streptococci is important in sustaining the physician's conviction for complete treatment.

Summary

In order to assess the effectiveness of the Minnesota Rheumatic Fever Secondary Prevention Program, the Minnesota Department of Health has been collecting data on reported recurrences of rheumatic fever and streptococcal infections in the 8,604 patients enrolled in the program from January 27, 1960 to January 27, 1964. Two hundred thirty-five recurrences were reported and detailed information was returned in 81.7 per cent (192). Of these 192, 63.2 per cent met Jones Criteria. The total recurrence rate per 100 patient years is 1.44 and the adjusted recurrence rate .93. Those rates compare with those reported in other programs.

Two hundred sixty-two streptococcal infections were reported. Of these 43 per cent (115) were followed by acute rheumatic fever. Comparing the groups that were with and without rheumatic sequelae it is noted that 17.4 per cent (20) and 30.7 per cent (45) had throat cultures taken. The importance of taking throat cultures to identify the beta hemolytic streptococci is emphasized because it sustains the necessity for ten full days of treatment of streptococcal disease.

Notice of Public Hearing
Minnesota State Board of Medical Examiners

"Notice is hereby given, pursuant to the provisions of Minnesota Statutes, 1961, S 15.0412, that the Minnesota State Board of Medical Examiners will hold a public hearing on Saturday, February 13, 1965, at 10 o'clock, A.M., in the auditorium of the State Office Building, Saint Paul, Minnesota, on the adoption of proposed substantive rules and regulations pertaining to professional corporations and to the practice of medicine and surgery, osteopathy, massage, physical therapy and midwifery, and of procedural rules and regulations pertaining to the hearing of contested cases before the Minnesota State Board of Medical Examiners.

Copies of the proposed procedural and substantive rules and regulations are available from the Secretary of the Minnesota State Board of Medical Examiners, 230 Lowry Medical Arts Building, Saint Paul, Minnesota, 55102.

Interested persons are invited to attend and submit data or views orally or in writing.

Dated at Saint Paul, Minnesota, this 23rd day of November, 1964.

By Order of the Minnesota Board of Medical Examiners

J. P. Medelman M.D.

Secretary-Treasurer"

Sure, maybe a machine could do your job. But when the boss talks, would it nod and listen? — Changing Times

May we have a minute of your time . . .

We would like your indulgence in filling out the questionnaire which is printed to the right of this article.

It will take only a few minutes. Just fill in the answers, tear off the card, fold it and have your office girl mail it. It is already addressed and stamped for return to us.

Your efforts will help us towards making MINNESOTA MEDICINE a better journal in 1965.

BOARD OF EDITORS
MINNESOTA MEDICINE

President's Letter Continued from Page 61.

medical family. Many of us practice in rural communities, while others serve in metropolitan areas. When the interests of all are considered, it is apparent that representing the physicians of Minnesota is a responsibility of considerable magnitude. Fortunately, past experience has shown that we work well together, have common interests, and possess an unsurpassed devotion to a high quality of medical care.

The year on which we are entering promises to be replete with the never-ending pressure to keep abreast of scientific advances while we struggle with difficult economic problems in a changing and sometimes critical society. I hope to make the office to which you have elected me representative, useful, and always available.

In Memoriam

Let death be daily before your eyes, and you will never entertain any abject thought, nor too eagerly covet anything.—Epictetus

HENRY W. WOLTMAN

Dr. Henry W. Woltman, one of the foremost neurologists in the United States and a former member of the Mayo Clinic, died November 27th of cardiac arrest due to calcific aortic stenosis. He was born at Westfield, Wisconsin, and received his doctor of medicine from the University of Minnesota Medical School.

Dr. Woltman was a former president of the Minnesota Society of Neurology and Psychiatry, the Central Neuropsychiatric Association, the Association for Research in Nervous and Mental Diseases and the American Neurological Association. He was a former president of the staff of the Mayo Clinic, a member of the advisory Council of the Neurological Diseases and Blindness Institute, United States Public Health Service and of the Medical Advisory Committee of the National Foundation for Infantile Paralysis. Also, Dr. Woltman was a fellow of the American College of Physicians, the American Academy of Neurology, a member of the American Medical Association, American Psychiatric Association, the Central Society for Clinical Research, Chicago Neurological Association, American Neurological Association, a former chairman of the Section on Nervous and Mental Diseases of the American Medical Association, a member of the Zumbro Valley Medical Society, and a 50 Club and Associate member of the Minnesota State Medical Association.

He is survived by his wife, a daughter and three sons.

LEO A. NASH

Dr. Leo A. Nash, 54, St. Paul radiologist, died December 1st in his home of a heart attack. He was born in Chisholm and received his medical and bachelor's degrees at the University of Minnesota, after which he had a fellowship in radiology at the Mayo clinic.

Dr. Nash was a fellow of the American College of Radiology, a past president of the Minnesota Radiological society and a member of the staff of the clinical institute of the University of Minnesota Medical School. He was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Nash is survived by his wife, four daughters and a son, Dr. Joel Nash of Albuquerque, New Mexico.

EMIL HABERMAN

Dr. Emil Haberman, 86, Osakis physician, died October 27th. He was born in Waterloo, Wisconsin; however, moved with his parents to South Dakota when he was five years old. He graduated from the University of Illinois School of Medicine, and after a few years went to Osakis where he practiced medicine for forty-three years.

In 1954 the village of Osakis honored his fifty years in the medical profession. He served many years on the Osakis school board of education and was an active member of the Osakis Booster Club and Chamber of Commerce. He was a member of the Stearns-Benton County Medical Society and the American Medical Association and a 50 Club and life member of the Minnesota State Medical Association.

He is survived by his wife, two daughters, and one son, Dr. George Haberman of Baltimore.

an effective
GERIATRIC
antiarthritic
with
REASSURING SAFETY FACTORS

Effectiveness, dependability and reassuring Safety Factors make PABALATE-SF a logical choice for antiarthritic therapy in elderly patients—even when osteoporosis, hypertension, edema, peptic ulcer, cardiac damage, latent chronic infection and other common geriatric conditions are present. The potassium salts of PABALATE-SF cannot contribute to sodium retention...the enteric coating assures gastric tolerance...and clinical experience shows that this preparation does not precipitate the serious reactions often associated with corticosteroids or pyrazolone derivatives.

Side Effects: Occasionally, mild salicylism may occur, but it responds readily to adjustment of dosage. Precaution: In the presence of severe renal impairment, care should be taken to avoid accumulation of salicylate and PABA. Contraindicated: An hypersensitivity to any component.

Also available: PABALATE—when sodium salts are permissible. PABALATE-HC—Pabalate-SF with hydrocortisone.

Pabalate-SF

A. H. ROBINS CO., INC., RICHMOND 20, VIRGINIA

In each persian-rose enteric-coated tablet: potassium salicylate 0.3 Gm., potassium aminobenzoate 0.3 Gm., ascorbic acid 50.0 mg.

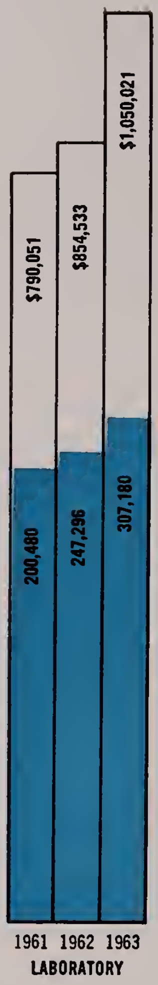
The 28th annual meeting of the New Orleans Graduate Medical Assembly will be held March 8-11, at the Roosevelt Hotel. Details of the New Orleans meeting are available at the office of the Assembly, 1430 Tulane Avenue, New Orleans, La. 70112.



Better Service, Doctor?

Yes, Blue Shield wants to serve Minnesota doctors even better than it has.

In 1963 Blue Shield paid for nearly 60,000 more laboratory services than it did in 1962. In dollars this was an increase of over $195,000.

If claims for laboratory services are submitted individually, and if they are paid individually, the cost to Blue Shield increases and the service to doctors suffers.

Collect your laboratory claims and submit them twice (preferrably once) a month. You will be paid promptly, and Blue Shield can operate more efficiently.

Photographic Contest

The Editors of MINNESOTA MEDICINE, in collaboration with the Doctors' Photographic Society of Minneapolis, take pleasure in announcing a monthly photographic contest. The contest is to promote an interest in photography in the medical profession. First prize each month will be publication in full color of the winning picture in MINNESOTA MEDICINE.

The following rules will govern the conduct of the contest:

1. Only doctors of medicine are eligible to submit pictures, and the picture must have been taken or composed by a physician.
2. Each contestant may submit not more than two pictures each month.
3. Only color transparencies, 35 mm. to 2¼″ can be considered.
4. Each slide should be labeled with the marker's name, address, and the identifying title.
5. Slides should not be mounted in glass, but can be protected in plastic sleeves or envelopes.
6. Each entry must be accompanied by a self-addressed, stamped envelope if return of the picture is desired. Returns will be made shortly after the close of the contest each month. The winning photograph will be retained but will be returned after it has been used.
7. The deadline date for entry will be the 10th of each month and the winner of each month's contest will be announced in MINNESOTA MEDICINE in the subsequent issue. The date of publication will be three to six months in advance.
8. There will be no limitation on subject material except as indicated in item 10.
9. Model releases will be requested of winners where appropriate.
10. Judges will be selected by the editors of MINNESOTA MEDICINE and the Doctors' Photographic Society. The judges will be guided by the precepts of the Photographic Society of America, and winners will be based on appropriateness, interest, impact, and technical excellence.
11. The editors of MINNESOTA MEDICINE and the Doctors' Photographic Society cannot be responsible for entries lost or damaged, but every effort will be made to protect submitted pictures.

Your pictures are hereby invited. Please submit pictures to:

History of Medicine

Andreas Vesalius

Founder of Modern Anatomy

Andreas Vesalius — pioneer, iconoclast, and "heretic" — was born a Belgian into the intolerant and dogmatic 16th century with its inflexible authoritarianism in the fields of science and religion. From early youth the study and demonstration of human anatomy was Vesalius' one passionate pursuit and purpose.

After studying medicine at Paris Vesalius went to Italy to lecture on anatomy at Padua, Pisa, and Bologna — all the while persisting in the dangerous and difficult practice of surreptitiously dissecting human cadavers, whenever available, in order to disprove Galen's erroneous theories of anatomy based on the dissection of lower animals.

Under the odium and stigma of iconoclasm and heresy Vesalius finally felt obliged to leave Italy; bequeathing his lectureship to his pupil Fallopius (of Fallopian tube fame), he went to France and later to Spain to act as court physician to Charles V and Philip II. But the sinister shadow of heresy for presuming to discredit and defy tradition pursued him, and in Spain he was tried by the Inquisition and condemned to death — like his predecessor Servetus, who had been burned at the stake for his numerous heterodoxies, such as maintaining that the blood passes from one side of the heart to the other side by way of the lungs rather than by osmosis, as Galenic medicine had established.

Vesalius' death sentence, however, was commuted on condition he make a devout pilgrimage to the Holy Land, which he did.

In the meantime the atmosphere in Italy was becoming more favorable to Vesalius' "revolutionary" theories and more conducive to such unorthodox practices as human corpse dissection, and Vesalius was invited back to Padua to resume his work there. But on the return voyage — through one of Fate's ironical whimsies — the shop was wrecked and Vesalius perished of starvation and exposure on the Island of Zante, thus depriving the world of the further potential of a brilliant and fearless mind.

Vesalius' "heresy" to medicine consisted in his deposing Galen as the sacrosanct authority in anatomy; His "heresy" to the Church consisted in his "impious" dissection of human bodies, thus making materially intact "resurrection" difficult — to say the least!

Because of Vesalius' iconoclasm: "The four abdominal muscles of the ape no longer graced man; the multi-lobed liver passed away, and so, too, did the segmented sternum, the double bile duct, and the horned uterus. With Galenic error went many ancient anatomical superstitions; the bone Luz, or the resurrection bone, was proved a myth, and Adam's missing rib was restored."*

Vesalius' distinguished work, "De Humani Corporis Fabrica," ranks as one of the great books of the 16th century.

Physician's Diary

No company is preferable to bad, because we are more apt to catch the vices of others than their virtues, as disease is far more contagious than health.—Colton

Dr. E. J. Tanquist, Sr. of Alexandria was honored at a dinner and presented with a plaque by the Kiwanis Club in recognition of outstanding service and leadership to the community.

* * *

Dr. Collin S. MacCarty, head of the section of neurologic surgery of the Mayo Clinic, was chosen president-elect of the staff of the Mayo Clinic at its annual meeting in November. Dr. MacCarty will take office in November, 1965. Dr. Howard P. Rome, senior consultant in psychiatry, who was named president-elect last year, assumed office this year.

* * *

Dr. H. Mead Cavert, assistant dean of the Medical School and University of Minnesota heart researcher, received an $85,000 grant from the Minnesota Heart Association to continue his research.

* * *

A plaque honoring the late Dr. **John M. Waugh**, a Mayo Clinic surgeon, was placed on the sixth floor of the Mayo Building by former Mayo graduate school of medicine fellows who served as his assistants. Dr. **Waugh** died in the summer of 1962 of injuries sustained in a traffic accident.

* * *

NEW LOCATIONS: Dr. **John Arnesen** of Owatonna has accepted a position as chief of the medical service at the Rochester State hospital . . . Dr. **T. J. Thompson** of Milaca left for LaPaz, Bolivia, with his family where they will be serving as medical missionaries in the Pfeiffer Memorial hospital . . . Dr. Reginald G. Bickford of the Mayo Clinic Electroencephalography Laboratories has left the clinic to do research at the Brain Institute, an affiliate of the University of California . . . Dr. **Charles G. Sheppard** of Hutchinson has joined the St. Peter State Hospital staff.

* * *

Dr. R. H. Wilson of Winona has retired from the practice of medicine in that city after thirty-four years of continuous service. Dr. and Mrs. Wilson will continue to live at their home at Queen's Cove, Lamoille, Minnesota.

* * *

Dr. **Joseph M. Janes**, consultant in orthopedic surgery in the Mayo Clinic and professor of orthopedic surgery in the Mayo Graduate School of Medicine, was elected president of the American Automotive Medical Association at its annual meeting.

* * *

Dr. Karl W. Anderson of Minneapolis was elected vice president and Dr. N. L. Gault, Jr., of the University of Minnesota Medical School was re-elected secretary-treasurer of the Minnesota Medical Foundation. The following physicians were elected to the group's board of trustees: Dr. **Dennis J. Kane** and Dr. **William Hartfiel** of St. Paul; Dr. **Cecil J. Watson** and Dr. **Arthur C. Kerkhof** of Minneapolis; and Dr. **Bernard Halper** of Hibbing.

* * *

Dr. Charles A. Neumeister of Edina has been elected to the board of directors of Blue Shield of Minnesota.

* * *

Dr. G. Roy Diessner, a Mayo Clinic consultant, was named president of the Zumbro Valley Medical Society at its meeting in November. Dr. F. Edmund Donoghue of Rochester was elected vice president; Dr. **Malcolm K. Campbell** of Rochester was elected secretary-treasurer, and Dr. **Robert E. Fricke** of Rochester was re-named executive secretary.

Of 1,021 children with various confirmed infections... 950 or 93.0% were treated successfully with Signemycin®

Note:
The effectiveness of Signemycin was demonstrated by Chattas and his co-workers* who administered Signemycin to 30 children with serious staphylococcal infections resistant to commonly used antibiotics. Only one failed to respond. In each case the use of this drug was indicated by antibiogram. Those children treated with a nonselected antibiotic—for comparative purposes—took three times longer to recover.

SIGNEMYCIN®

Side Effects: Glossitis and allergic reactions, as well as severe anaphylactoid reactions, have been reported as rare side effects. Should significant reaction or idiosyncrasy occur, discontinue medication and institute countermeasures. Use of tetracycline during the last trimester of pregnancy, neonatal period and early childhood may cause discoloration of developing teeth. Reduce usual oral dosage and consider serum level determinations in patients with impaired renal function to prevent possible liver toxicity due to excessive accumulation of antibiotic in the serum.

Precautions: Overgrowth of nonsusceptible organisms may occur. In such cases, discontinue medication and institute appropriate specific therapy as indicated by susceptibility testing. Aluminum hydroxide gel given with antibiotics has been shown to decrease their absorption and is contraindicated. The coloring agents used in Signemycin Syrup and Pediatric Drops may produce red discoloration of stools.

Triacetyloleandomycin, a constituent of Signemycin, administered to adults in daily oral doses of 1.0 Gm. (3 Gm. Signemycin) for periods of more than ten days may produce hepatic dysfunction and jaundice. In the rare patient who requires this high dosage level of Signemycin initially, liver function should be carefully followed and dosage should be reduced, as promptly as possible, to the usual recommended range of 1.0 to 2.0 Gm. per day. Therefore, Signemycin is recommended primarily for the treatment of acute or severe infections, with treatment restricted to a ten-day period. If clinical judgment dictates continuation of therapy beyond ten days, serial monitoring of the liver profile should be carried out, including BSP, transaminase, and cephalin flocculation tests. Changes observed in liver function were reversible following discontinuation of the drug.

Formulas: Capsules: 250 mg. Signemycin (167 mg. tetracycline HCl and 83 mg. oleandomycin as triacetyloleandomycin).

Capsules: 125 mg. Signemycin (83 mg. tetracycline HCl and 42 mg. oleandomycin as triacetyloleandomycin).

Syrup: 125 mg. Signemycin (tetracycline equivalent to 83 mg. tetracycline HCl and 42 mg. oleandomycin as triacetyloleandomycin) per 5 cc.

Pediatric Drops: 100 mg. Signemycin (tetracycline equivalent to 67 mg. tetracycline HCl and 33 mg. oleandomycin as triacetyloleandomycin) per cc.

PFIZER LABORATORIES Division, Chas. Pfizer & Co., Inc. New York, New York 10017

®

Of 5,057 patients with confirmed infections of all body systems... 4,731 or 93.5% were treated successfully with Signemycin®

Note:

The high rate of response to Signemycin in these cases is noteworthy because the totals include many patients with difficult-to-treat infections, many whose infections had proved resistant to other agents, and many who had been treatment failures on other therapy.1-87 In addition the following criteria were used for the cases cited: (1) only published results were used (2) results were confirmed by clinical and/or laboratory findings (3) patients were cured, not "improved" (4) dosage conformed with current recommendations in the United States (5) no other anti-infective agents were used concomitantly (6) no instance of prophylactic use was included in these tabulations.

Condition	No. of Patients	No. Responded To Signemycin
Ear, nose and throat infections	507	465
Respiratory infections	1,028	954
Gastrointestinal infections	425	387
Genitourinary infections	748	684
Skin and soft-tissue infections	1,088	1,036
Bone and joint infections	71	64
Deep-seated or generalized infections	257	251
Obstetrical & gynecological infections	341	320
Miscellaneous conditions	592	570
Totals	5,057	4,731 (93.5%)

consistently effective...often when others fail

Signemycin®

Hygroton®
brand of chlorthalidone
the long-acting diuretic

Indications
Many types of edema involving retention of salt and water.
Contraindications
Hypersensitivity, and most cases of severe renal or hepatic disease.
Precautions
Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Side Effects
Constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, leukopenia, muscle cramps, nausea, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.
Average Dosage
One tablet (100 mg.) daily with breakfast.
Availability
Tablets of 100 mg. in bottles of 100 and 1000.
For full details, see the complete prescribing information.

Geigy Pharmaceuticals
Division of
Geigy Chemical Corporation
Ardsley, New York

How does Hygroton® brand of chlorthalidone stack up against other diuretics?

Not very high. In terms of one week's therapy, that is. The usual dosage is just one tablet per day. Very often, the dosage is even lower. So a week's therapy doesn't amount to much.

That's why it's nice to work with Hygroton®, brand of chlorthalidone. You have fewer tablets to prescribe. Your patients have fewer tablets to take. And fewer to pay for.

For sheer diuretic effectiveness, choose Hygroton®, brand of chlorthalidone. It generally promotes more natruresis per tablet than the thiazides. We'll stack it up against any diuretic.

epilepsy may limit
opportunity...

Dilantin®
(diphenylhydantoin)
PARKE-DAVIS

extends horizons

This agent "...has brought new hope to an entire generation of seizure patients....With judicious use, it may be said that it alone is responsible for the prevention of more seizures than any other drug."*

DILANTIN (diphenylhydantoin) can help your epileptic patient to earn a livelihood...to prove his worth...and to share in the daily give-and-take as a full-fledged member of the workaday world.

Indications: Grand mal epilepsy and certain other convulsive states.

Precautions: Toxic effects are infrequent: allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Eruptions then usually subside. Though mild and rarely an indication for stopping dosage, gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered, especially in children, adolescents, and young adults. During initial treatment, minor side effects may include gastric distress, nausea, weight loss, transient nervousness, sleeplessness, and a feeling of unsteadiness. All usually subside with continued use. Megaloblastic anemia, aplastic anemia, leukopenia, granulocytopenia and pancytopenia have been reported. Nystagmus may develop. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. Periodic examination of the blood is advisable.

DILANTIN (diphenylhydantoin sodium) is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm.

PARKE-DAVIS

PARKE, DAVIS & COMPANY, Detroit, Michigan 48232

to help restore and stabilize the intestinal flora
for fever blisters and canker sores of herpetic origin

LACTINEX®

TABLETS & GRANULES

LACTINEX—a viable culture containing both *Lactobacillus acidophilus* and *L. bulgaricus*—was first introduced to help restore the flora of the intestinal tract in infants and adults.[1, 2, 3, 4]

Further clinical work showed LACTINEX to be successful in the treatment of fever blisters and canker sores of herpetic origin.[4, 5, 6, 7]

No untoward side effects have been reported in 12 years of clinical use.

Literature on indications and dosage available on request.

A rhinologic approach to the sinuses
Sagittal anatomical section of nasal cavity showing approach for probing or irrigation by cannulas.

A—Sphenoid: A sphenoid cannula (under 13.5 cm.) passed around the middle and superior turbinates to the anterior wall of the sinus through its ostium.

B—Maxillary: A conventional antral cannula passed beneath the middle turbinate, over the uncinate process, and rotated downward and laterally into the ostium.

C—Frontal: A conventional antral cannula passed after preliminary maneuvers through the frontonasal canal into the ostium frontale.

In colds and sinusitis Neo-Synephrine® sooner

hydrochloride
(Brand of phenylephrine hydrochloride)

can help prevent emergency measures later

Before complications arise in colds and sinusitis, Neo-Synephrine solutions and sprays reduce nasal turgescence on contact—to promote essential aeration and drainage. Turbinates shrink, sinus ostia open and drainage is freed. Relief is instant and the threat of complications is lessened.

In the treatment of sinusitis, the ¼ per cent solution is a preferred vasoconstrictor, "...most closely approximating physiologic composition with the least 'rebound' tendency...."* Gentle Neo-Synephrine is well tolerated by delicate respiratory tissues. Systemic effects are practically nil, post-therapeutic turgescence is minimal and repeated applications do not lessen its effectiveness. Neo-Synephrine has been a standard among vasoconstrictors since 1935.

Available in plastic nasal sprays for adults (½%) and children (¼%), in solutions of ⅛, ¼ or 1 per cent.

GENERAL INFORMATION

Authors

Manuscripts for consideration in Minnesota Medicine should be addressed to Office of Publication, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Papers should be typed double spaced on white paper with a wide margin. The first page should list the title, the name of the author (or authors), degree, and any institutional or other credits. Pages should be numbered consecutively. Tables should be typed and numbered and should have a brief descriptive caption.

Bibliographical references should be limited to twelve and should be typed in conformity to the method used by the Index Medicus. They should be numbered consecutively in the order in which they first appear in the text. Book references should give the name of the author, title, edition number, publisher, and the year.

Illustrations (photographs, tables, and graphs) should be submitted on separate sheets of paper and not combined in the text. Instructions for combining photographs are acceptable.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association of any of its constituents.

President's Letter

It is apparent to the physician who reads the current literature on medical economic problems that the cost of health care is of great concern to the American public and its elected representatives in government at all levels. The most rapidly rising factor is the cost of hospital care, which now amounts to more than a third of the total cost. Those who have to do with hospital care naturally concern themselves with all phases of this cost. Efficient use and location of hospital facilities are imperative if costs are to be controlled. Therefore, the adequate planning of hospital construction in geographic areas large enough to be effective is most important.

The American Medical Association has made its position on area-wide hospital planning clear in a series of resolutions passed by the House of Delegates in the years 1962, 1963 and 1964. State and county medical societies and individual physicians are encouraged to participate in the formation and operation of regional hospital-planning bodies under a voluntary system. The dangers inherent in enabling legislation, which would establish a compulsory system, are emphasized. The recently enacted Metcalf-McCloskey Bill in New York is an example of such legislation.

Under the Hill-Burton Act there are funds available for the establishment of planning agencies at state and county levels. This act has served as a stimulus, so that communities in which planning agencies have functioned now contain about 40 per cent of the nation's physicians. These communities are, for the most part, in urban centers. In Minnesota there are planning councils in Minneapolis, St. Paul and Duluth which are operating by means of grants from the Public Health Service to the State Department of Health. These grants are about to expire. The Minnesota Hospital Association is proposing the creation of a state-wide planning committee and has invited the Minnesota State Medical Association to share the responsibility jointly with it and with the State Board of Health. In the past the State Board of Health, as a result of its administration of Hill-Burton funds and its licensing power, has been the major element in the planning and approval of hospital facilities. The proposal of the Minnesota Hospital Association is welcomed by the State Board of Health because it adds the desirable element of representation from the medical and hospital professions. The Minnesota Hospital Association also proposes to join with the Minnesota State Medical Association to assist in the establishment of voluntary local and area-wide planning councils for hospitals and related health facilities. In addition, the activities of established planning agencies would be coordinated. At its December meeting the council of the Minnesota State Medical Association approved such action for a year's trial, and referred the plan to the Committee on Hospital and Professional Relationships for development.

With the full approval of the American Medical Association, the American Hospital Association and influential business leaders, there seems little doubt that area-wide hospital planning will proceed. Physicians must be a major force in working with responsible

therapeutically
the *Most* active
erythromycin

In the patient, Ilosone *eradicates*, rather than merely inhibits, streptococci and pneumococci. This increased action is due to the fact that more erythromycin reaches the infection site because Ilosone (1) is acid stable in the stomach, even in the presence of food, and (2) is better absorbed from the intestine.

Ilosone produces peak levels of antibacterial activity *two* to *four* times those of other erythromycin preparations. Furthermore, these peak levels are attained earlier with Ilosone and are maintained much longer.

Side-Effects: Even though Ilosone is the most active oral form of erythromycin, the incidence of side-effects is low. Infrequent cases of drug idiosyncrasy, manifested by a form of intrahepatic cholestatic jaundice, have been reported. There have been no known fatal or definite residual effects. Gastro-intestinal disturbances not associated with hepatic effects are observed in a small proportion of patients as a result of a local stimulating action of Ilosone on the alimentary tract. Although allergic manifestations are uncommon with the use of erythromycin, there have been occasional reports of urticaria, skin eruptions, and, on rare occasions, anaphylaxis. **Contraindications:** Ilosone is contraindicated in patients with a known history of sensitivity to this drug and in those with preexisting liver disease or dysfunction. **Dosage:** *Children under 25 pounds*—5 mg. per pound of body weight every six hours. *Children 25 to 50 pounds*—125 mg. every six hours. *Adults and children over 50 pounds*—250 mg. every six hours. For severe infections, these dosages may be doubled. Ilosone Chewable tablets should be chewed or crushed and swallowed with water.

Radiation in Pregnancy*

KARL K. LATTEIER, M.D.**
LAWRENCE O. GARBER, M.D.***
Detroit, Michigan

A FEW years ago, when fallout from atomic tests triggered a radiation scare, the danger of radiation in pregnancy became so exaggerated that the use of X-ray diagnosis was temporarily abandoned by many doctors. However, it was soon discovered that X-ray examination was necessary to maintain obstetrical standards and to prevent fetal loss and maternal complications.

The widespread publicity of radiation dangers, however nebulous they may be, has served a good purpose. It has united the medical professions and allied agencies to develop a high standard of radiation protection. It has stimulated enactment of laws prohibiting dangerous and unwarranted lay use of radiation. Manufacturers have developed safer and more effective shielding for X-ray equipment. Manufacturers of films have developed high-speed film and cassettes with improved developing technique reducing X-ray exposure. Today radiation is a valued diagnostic tool, essential to modern medical practices. Indirectly it saves innumerable lives daily, through its diagnostic and therapeutic application.

Today the use of medical radiation is increasing. The expansion in hospital construction and facilities has increased the availability of radiological facilities to patients. There has also been greater insurance coverage for radiological examination. Further, the advance in medical science has opened new fields of radiation diagnosis and treatment. The technique which enables the radiologist to visualize the blood vessels in almost any part of the body by the introduction of a contrast medium is becoming commonplace even in small hospitals away from the medical centers. Radioactive isotopes can be introduced into the body by vein or through the intestinal tract, systematically traced to various parts of the body, and their absorption and excretion accurately calculated. Additional physicians are continually being licensed to use isotopes. Isotope labs are no longer limited to hospital radiological departments but are now available in offices and clinics.

Such new applications of radiation have already been used in the care of the pregnant patient. For example: placental visualization which was formerly a complicated film study can now be easily demonstrated by a single X-ray film, by isotope radiation studies, by aortography, and by injection of contrast media into the amniotic sac. However, the additional stress of pregnancy may aggravate pre-existing heart, thyroid, lung, kidney or intestinal diseases, requiring additional radiation studies. It is important, therefore, to use radiation sparingly, selecting it only for the most urgent needs throughout the pregnancy. Let us curtail our enthusiasm for diagnostic radiation procedures having only an academic interest, and let us limit their use to physicians with sufficient interest in their profession to maintain adequate safe guards.

---

*Presented at the Minnesota State Medical Association Annual Meeting in Rochester, May 19, 1964.

**Department of Radiology, Crittenton Hospital of Detroit.

***Department of Obstetrics and Gynecology, Crittenton Hospital of Detroit.

Currently a survey is being conducted jointly by the division of Radiological Health and the National Health Survey under the auspices of the United States Public Health Service. The object is to eliminate unnecessary radiation exposure, but may actually result in restrictions in medical use of radiation. If we wish to keep radiation protection and control under medical supervision and prevent unwarranted or unreasonable government control, we must avoid all unnecessary radiation in any form.

How Safe and How Harmful is Radiation in Pregnancy?

Radiation, like drugs, foods, or anything else, is dangerous if you get too much of it. Therefore the most obvious method of protection must be by measuring and limiting its use. Radiation disrupts molecules, thereby injuring cell function; this may be desirable in therapy, but obviously is not for use in diagnosis.

Everyone is aware of the hazards of large amounts of radiation, but we do not know the effects of small doses. We state that there are somatic and genetic hazards as a result of radiation in small amounts and to limited portions of the body. In theory and from insect and animal experimentation the greatest genetic effect appears to be the addition of undesirable mutants through radiation exposure of the gonads. This effect is thought to be cumulative, and there appears to be no threshold below which radiation can be considered safe. Now this involves the segment of the population including both the mother and the fetus. Therefore, much objection to radiation in pregnancy is derived from this source.

The Somatic Hazard

Since the radiation effect is disruption of the molecules, even a diagnostic X-ray procedure must produce some cell damage. Diagnostic exposures may vary from a few milliroentgens to several roentgens. However, the somatic effect may be limited by a threshold below which radiation injury to the cell is sublethal and partial or total cell recovery occurs. This threshold in humans is still unknown; but it has been learned from rodent and other animal experimentations that as little as twenty-five rads absorbed by the developing embryo at its most sensitive stage, from conception to three months, may produce malformations. No developmental change can be produced by radiation, however, after a period of six weeks gestation, because by that time all of the organ systems have formed. Larger amounts of radiation are then required to produce an undesirable effect.

We must remember that during the entire pregnancy, radiation of the mother's abdomen constitutes whole body radiation of the fetus, and during the first trimester embryonic tissues show an increased cell sensitivity at least double or possibly three or four times that of the mother. Another question arises as to whether or not diagnostic studies during pregnancy increase the incidence of neoplasm, especially leukemia, in the offspring. Statistical evidence has been presented to support the contention that no neoplastic increase or carcinogenesis is attributable to diagnostic radiation. Large studies, especially the report which surveyed nearly 40,000 individuals who had been subjected to diagnostic X ray while in utero showed that the incidence of leukemia was not greater than that in the general population.

What Can We Do to Protect the Pregnancy?

Elective X-ray Examination During the Menstrual Period

The general use of roentgen examination as a diagnostic study apart from pregnancy with inadvertent radiation in early pregnancy before it is recognized by the patient or by the physician may constitute the greatest hazard of radiation in pregnancy; this hazard, however, can be largely eliminated by having such elective radiological examinations, especially when fluoroscopy or multiple exposures are involved, made during the menstrual period or the ensuing two weeks.

Avoid Radioactive Isotopes

It is our policy to avoid the use of radioactive isotopes in treatment or diagnosis of hyperthyroidism during pregnancy, since in early pregnancy it is undesirable from the standpoint of the sensitivity of the fetus, and in later pregnancy it is undesirable due to the fact that the fetal thyroid may concentrate and retain radioactive iodine which could result in a hypothyroid fetus.

Use Semi-opaque Plastic Filter

In the later part of pregnancy, especially in the last trimester, total body irradiation of the fetus may be minimized by the use of semi-opaque plastic filters shaped to avoid over-exposure of the thin part and reduce the amount of radiation, yet still allow sharp definition of the cleavage planes permitting visualization of the urinary bladder, placenta, and bone structures of the pelvis with one film exposure of much less than an average absorbed radiation dose. The filters prevent the soft rays, which do not aid in exposure of the film, from entering the tissues. Grossly over-exposed film or a retake study destroys the value of low dosage technique; improper positioning and other technical factors reducing diagnostic accuracy are to be avoided by certainty that work is done by competent personnel.

What are Considered to be Justifiable Roentgen Studies During Pregnancy?

In many states the premarital examination is required by law, and we should use this opportunity to examine our patients thoroughly. The premarital examination also offers an excellent opportunity for the doctor to acquaint his patient with the medical concepts of radiation in pregnancy and to advise the patient to have routine chest study and radiological investigation of urinary or gastrointestinal tract, if indicated, prior to conception.

Avoid X ray During First Trimester

At the patient's first prenatal visit, a chest film is not necessary. This is especially true if she presents herself for care in the first trimester. Initially, a tuberculin test can be made. Chest X rays are then indicated on the positive reactor. We prefer a large chest film to a photofluorogram which requires four to 10 times as much exposure and is less reliable. Also, no permanent record results if only a photofluorogram is used. Radiological work-up of other problems found in the first prenatal visit can usually be postponed until after delivery or at least until the second or third trimester. Gastrointestinal and urologic studies are especially to be avoided, and it is not necessary to subject the patient to radiation merely because of pyelitis. With suspicion of malignancy, roentgen study is probably justified. Fortunately it is rare in this age group.

Threatened abortion is perhaps the most common problem in the first trimester, but here again X ray is of no use. In the question of *ectopic pregnancy,* radiologic methods, with the exception of arteriography, have not been reliable. Culdocentesis and culdoscopy appear safer and are more accurate. In cases where *hydatiform mole* is suspected, serial gonadotropic assay is done to establish the diagnosis. Here roentgen studies are usually helpful only after the pregnancy is of four to six months' duration; even then the presence of a fetus may confuse the issue, as a mole can co-exist with a fetus.

X ray During Second Trimester

Hydramnios should certainly be investigated, as fetal anomaly is often responsible and easily found by roentgen study. Abdominal pregnancy is rare; to be certain, however, the diagnosis may be lifesaving. Film studies are helpful especially if a sound or contrast medium is placed in the uterus, as the abdominal gestation can then be clearly demonstrated. *Multiple pregnancy* in the second or third trimester can be easily diagnosed by a single film exposure. Second trimester *intrauterine fetal death* can usually be diagnosed by clinical means and fetal electrocardiography, but Roentgen confirmation in five to seven days after death is helpful and quite accurate. It may support a clinical diagnosis of fetal death even earlier.

X ray During Third Trimester

The etiology of bleeding in the second trimester is very difficult to diagnose by routine radiologic studies. It is probably in this area that special studies such as *arteriography and isotope studies* will prove more valuable. It is indeed fortunate that the radiologic studies in pregnancy are most valuable and accurate in that portion of pregnancy where they are the safest, namely, in the third trimester. Certainly previously mentioned conditions such as hydramnios, multiple pregnancy, fetal death, and abdominal pregnancy may first be suspected or diagnosed in the third trimester.

Pelvimetry is most valuable if done on the patient when she is in labor. Roentgenograms using a standing film can readily be taken during labor. In reviewing our staff cases we find that less than half of the patients where dystocia is suspected by clinical means, will actually require pelvimetry, provided one waits for the onset of labor before ordering the films. Certainly if difficult or mid-forceps delivery is contemplated, the forceps can be applied more intelligently if the fetal position and pelvic architecture are known. When a patient in labor stops making progress, the diagnosis of inertia cannot be made until disproportion is ruled out. Pitocin is a great aid in the management of inertia but may be a great tragedy in disproportion. This is certainly true in a primigravida or even in a multipara who may have delivered a small baby but cannot deliver the larger fetus.

In early labor, pelvimetry is indicated to explain *the unengaged head,* especially in a primigravida, and also in the primigravida breech. However, roentgen examination in all breech presentations prior to term is not indicated, since spontaneous conversion to vertex is common.

Placentography in the third trimester may eliminate the need for a double set-up for management of *uterine bleeding near term.* The double set-up in itself may force one's hand to an immediate cesarean section, even with a grossly premature fetus. X ray offers an accurate and safe way to make the diagnosis without the risk of hemorrhage. Since the initial bleeding is usually not severe, we are able to treat the patient expectantly and perhaps gain two or three weeks of additional intrauterine life for the fetus, or an increase of six to eight ounces in weight, by keeping the mother at bed rest and prepared for emergency surgery. *When a patient bleeds in the last trimester the differentiation between placental separation and placenta previa must always be made.* Prolonging intrauterine life in placental separation may induce fetal death. Usually the diagnosis can be made accurately on the basis of a single lateral film. If placenta previa is not present, the diagnosis is most commonly abrupto or marginal sinus separation. Then a vaginal examination can be done and the mode of delivery decided upon, based on the status of the fetus, the status of the cervix, and the convictions of the obstetrician involved. It is our feeling that placentography is more valuable than isotope studies in evaluation of placental location at term. The isotope studies locate the placenta as to whether it is on the right or on the left, but this is probably of very little clinical significance. The other advantage of placentography at term lies in the additional information that we can derive, such as the position and maturity of the fetus, and whether or not there are any congenital abnormalities present.

Should Routine Films for Fetal Age and Size Be Done?

There is no point in doing routine films long before term, as they will only have to be repeated. If the obstetrician plans a cesarean section at 38 to 40 weeks, he should have roentgen consultation only if he is concerned about the fetal size or length of gestation. In a recent review of our cesarean sections, we have found no prematures resulting from scheduled repeat sections at 38 to 40 weeks even though no radiological studies were made. Obviously, if a cesarean section is to be done prior to term for diabetes, toxemia, or Rh incompatability, a film for fetal age and size is of great value.

Discussion

There seems little doubt that modern diagnostic radiology used intelligently in the obstetrical care of patients can keep alive mothers and babies who otherwise would die. Practically, we have no personal knowledge of neoplasm or fetal malformation resulting from the use of diagnostic roentgen procedures in our practice. We are certain that we have saved both mothers and infants by judicious and carefully applied roentgen studies of high technical quality. It is a mistake to allow the technician who is not well versed in technique to utilize this procedure, and it behooves the radiologist and the obstetrician to learn as much about these subjects as possible in order to obtain the maximum amount of information from each film.

Those of you who can remember birth injuries realize that a fetus damaged as the result of trauma sustained during delivery is a burden on society and the immediate family greater than the radiation danger in any form. Markedly prolonged labors that have been terminated by difficult forceps deliveries have largely disappeared. Surely cesarean section is an entirely safe procedure and the indication for cesarean section is frequently determined by the roentgen study. There are usually no contraindications to a trial labor if it seems desirable, but even this might be avoided by proper roentgen examination. A single lateral view at approximately 36 weeks of gestation in repeat sections makes it possible to increase the over-all birth weight by eliminating prematurity in elective section. With the use of X ray it is possible to avoid section in instances of fetal malformation, and fetal death can be diagnosed before the clinician is aware of this complication.

Summary

One of the greatest hazards of radiation in pregnancy can be eliminated by conducting extensive elective radiological examinations during the menstrual period and the ensuing two weeks. During pregnancy, the management of the prenatal period and labor may be safely conducted, using radiological procedures as necessary when radiation control and protection assure the safety of the mother and fetus. The need for each radiological examination should be carefully evaluated.

No specific procedure can be condemned if it is sufficiently indicated for the good of the mother or the infant.

ABDOMINAL MIGRAINE SYNDROME

Abdominal pain, nausea, vomiting, and occasional diarrhea are occasionally a conspicuous part of the clinical picture of migraine headache. This has been principally seen in children or young adults who have had migraine headaches for years.

The parenteral administration of ergotamine usually causes prompt subsidence of the symptoms. Desensitization with intravenous histamine has been found to provide prolonged relief.

Evaluation of a New Bronchographic Medium

Ever since 1922, when Sicard and Forestier[1] introduced the use of iodized peanut oil in clinical bronchography, clinicians have sought the ideal bronchographic medium. In order for a material to qualify as a good substance for use in bronchography, it must (1) be sufficiently radiopaque to provide good contrast on thoracic roentgenograms, (2) be able to coat the inner surface of the bronchial tree so that good anatomic detail can be delineated on roentgenographic examination, (3) be nonirritating to the respiratory tract, (4) be easily and quickly eliminated from the lungs, and (5) be incapable of producing either transitory or permanent toxic changes in the lungs.

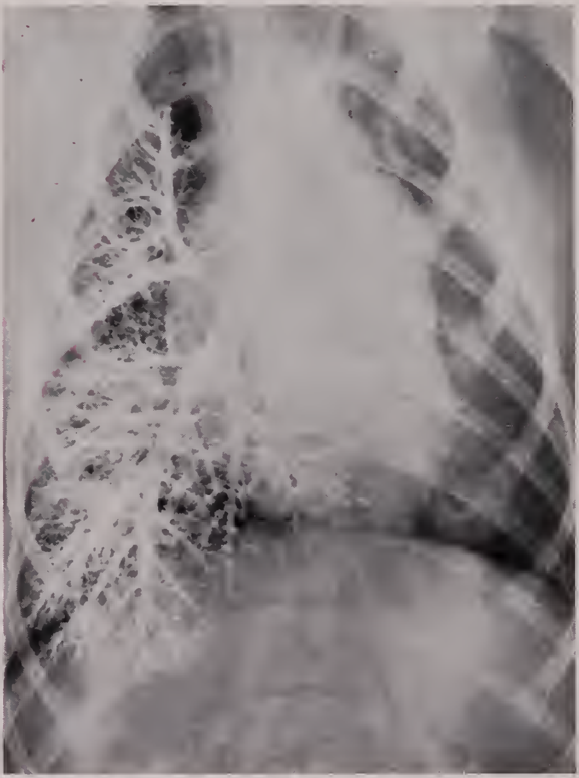

Fig. 1 *(a)* — Contrast produced by medium studied.

Much has been written concerning the efficacy of various media used in bronchography. We recently have encountered a medium which renders excellent bronchial detail on roentgenograms and, therefore, undertook a study of its potential toxicity. We think that any new medium should be thoroughly studied for possible untoward reactions, and we would like to discuss a method that we employed in evaluating such a medium.

Methods

Five mongrel dogs were anesthetized lightly with thiopental (Pentothal), and a tracheal catheter was inserted in each dog. In four animals, 5 ml. of a water-soluble bronchographic medium was instilled into the right side of the bronchial tree. In the other dog, 5 ml. of an oil-base medium (propyliodone [Dionosil]) was used in the same manner.

An Experimental Study

Anteroposterior bronchograms were made, the dogs were placed in a head-down position to allow the media to drain from the lungs, and the animals were allowed to recover from the anesthetic. Roentgenograms were made the next morning for evidence of retained material.

One animal was sacrificed two days and one six weeks after bronchography. Two animals had right lower lobectomy 48 hours after bronchography. One of these was necropsied 10 days after operation, and the other, six months later. The animal exposed to the oil-base medium was sacrificed two days after bronchography.

In each case, the lungs were examined for the presence of foreign material, and sections of tissue from the basal segments and from the superior segment of the lower lobe were stained with hematoxylin and eosin. Fresh-frozen sections were stained for fat and were examined microscopically. Each section was examined under polarized light for evidence of retained material.

Results

All animals survived the bronchographic procedure. Of the two dogs subjected to right lower lobectomy, one survived and was sacrificed six months later; the other grew lethargic seven days postoperatively, became febrile, and died on the tenth postoperative day.

The bronchographic detail made possible by the new medium is illustrated in Figure 1*a*. The outline of the bronchial tree is considered to be somewhat superior to that obtained by the use of the oil-base medium (Fig. 1*b*).

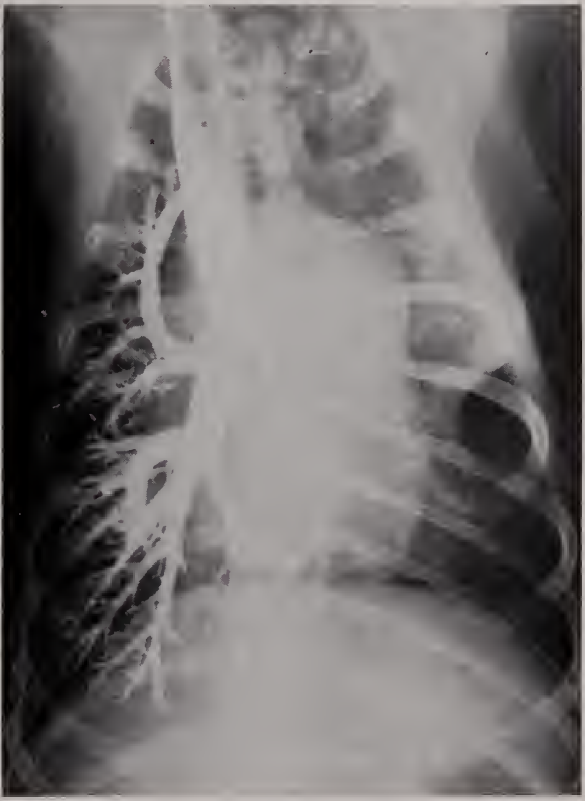

Fig. 1 *(b)* — Contrast produced by oil-base medium.

Roentgenographic Findings 24 Hours After Bronchography

Of the four animals exposed to the new medium, only one showed evidence of retained medium in the lungs the next morning (Fig. 2), and it was this animal that died 10 days after lobectomy, apparently of pneumonia and empyema. The animal exposed to the oil-base medium did not have demonstrable radiopaque material in its lung 48 hours after bronchography.

Pathologic Findings

Forty-eight hours after bronchography examination of the lower lobe of the right lung showed medium to be present both grossly and microscopically in one of three animals examined. The heaviest concentration was seen in the basal segments of the lower lobe, with moderate amounts in the superior segment. The material was found to be doubly refractile on microscopic examination and could be identified easily when viewed with polarized light. Numerous particles of medium were identified microscopically in the bronchi of the lower lobe and in a hilar node removed at the time of operation (Fig. 3). Associated with the deposition of medium within the lung was a moderately severe inflammatory reaction, particularly marked in the peribronchial regions (Fig. 4). The two other animals examined at this time did not show evidence of retained medium either grossly or microscopically, but microscopic examination of tissue from the basal segments and superior segment showed responses that varied from mild inflammation and atelectasis to patchy pneumonitis and bronchopneumonia (Fig. 5). Associated with the pneumonic change was some hyperplasia of bronchiolar epithelium (Fig. 5*b*). The irritative effect was evident predominantly within and around terminal bronchioles and alveolar ducts rather than in relation to the larger bronchi (Fig 5*a* and *b*). The lung of the dog exposed to the oil-base medium and sacrificed two days later showed no gross abnormality, and little or no inflammatory reaction could be demonstrated microscopically.

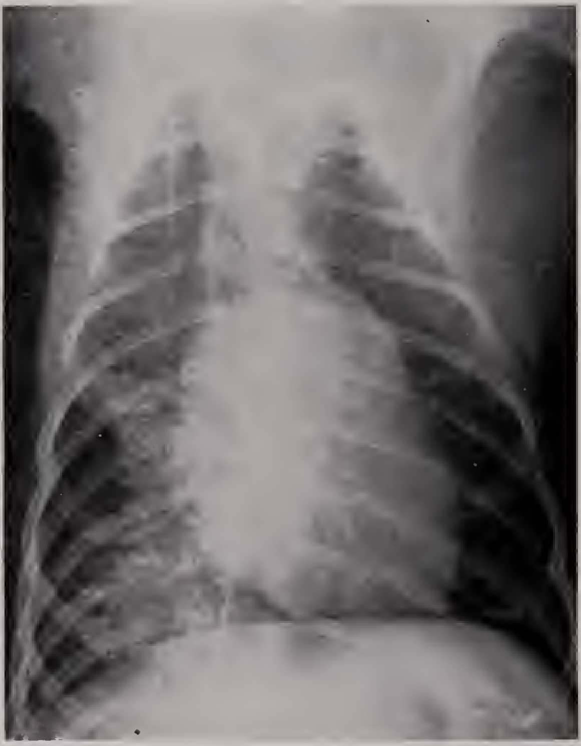

Fig. 2 — Roentgenogram taken 24 hours after bronchography showing retention of medium in the right lung.

At 12 Days After Bronchography.

Examination of the left lung and the remaining part of the right lung of the dog that died 10 days after lobectomy revealed that the cause of death was undoubtedly a fulminating pneumonia. The right pleural space was filled with purulent exudate, the right lung was hyperemic and heavy, and purulent material could be expressed from the parenchyma. The left lung also was involved in the inflammatory process. Microscopically, medium could be seen in the parenchyma and in some of the larger bronchi. The inflammatory reaction was intense and was associated, in many regions, with deposits of bronchographic medium.

At Six Weeks After Bronchography

No medium could be identified on gross or microscopic examination of the lung at this time. Some residual inflammatory reaction was noted, predominantly peribronchial in distribution (Fig. 6).

At Six Months After Bronchography

No gross changes were present in the remaining lung tissue. No medium could be

identified microscopically. The microscopic findings consisted of focal areas of interstitial pneumonitis with some thickening of alveolar walls and some peribronchial fibrosis (Fig. 7).

Comment

It is generally recognized that whenever bronchography is performed, a certain optimal period should pass before operation is carried out. The exact length of this period is a subject of considerable controversy. Studies have been made that suggest that the changes in pulmonary function which occur after bronchoscopy disappear after 48 hours when iodized oil is used as the medium, even though there is roentgenologic evidence of retained medium.[2] In patients with advanced pulmonary disease, however, retention of iodized oil may affect gas exchange significantly.[3]

Studies carried out with iodized oil as the contrast medium have shown persistent pathologic changes within the lung parenchyma. Medium could be identified on thoracic roentgenograms months after it had been instilled in the bronchial tree.[4,5] Various water-soluble media have been studied and found to produce a variety of parenchymal lesions.[6,7] These were often manifested, after bronchography, by clinical symptoms such as fever and increased pulse and respiratory rates.[8] Oily propyliodone (Dionosil) seems to produce the least irritative response in the respiratory tract, the effects being similar to those induced by physiologic saline.

The particular medium used in this study provoked a considerable irritative response from the respiratory tract of a dog, the major part of which was seen in the terminal bronchioles and alveolar ducts. The fact that this medium was birefractile made identification of it in the tissues relatively easy. Even the smallest particles could be seen readily. Although it has been reported that the material is not cleared from the lung by way of the lymphatic system, it is interesting to note that, with the polarizing light microscope, medium was seen in the hilar nodes removed

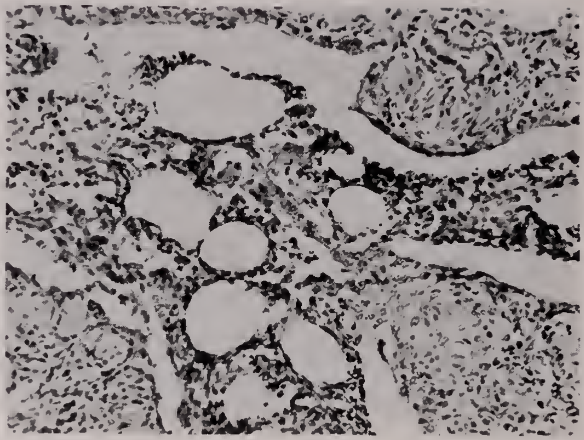

Fig. 5 *(c)* — Higher power view of same area shown in 5 *(b)* showing exudate in the lumen (hematoxylin and eosin; x400).

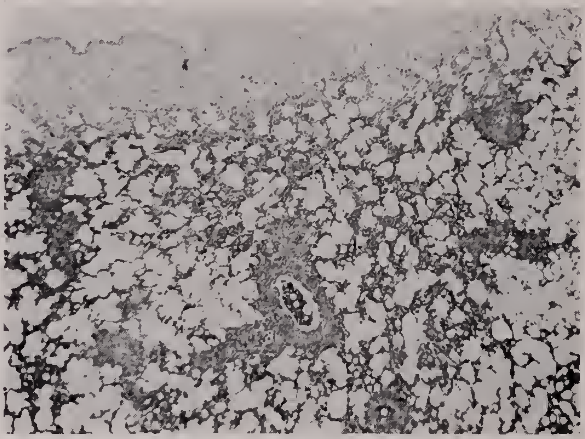

Fig. 6 — Section of lung removed six weeks after bronchography. Inflammatory reaction persists, and there is some peribronchiolar reaction with exudate still present in the lumen of the terminal bronchioles (hematoxylin and eosin; x25).

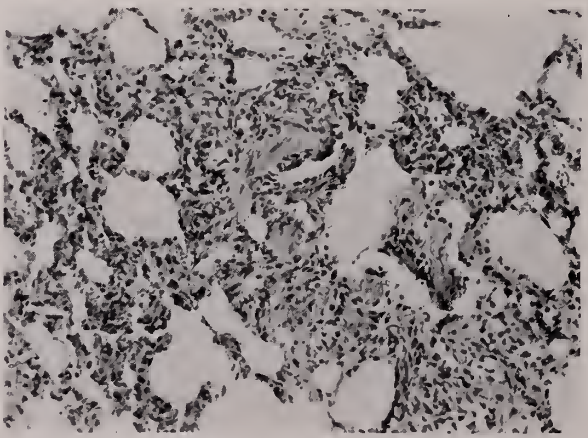

Fig. 7 — Section of lung removed six months after bronchography. Note areas of patchy fibrosis (hematoxylin and eosin; x200).

48 hours after bronchography had been performed.

The histologic findings of parenchymal fibrosis in the dog that was sacrificed six months after bronchography suggest that some permanent damage can occur in the lung exposed to this bronchographic medium, even though this damage may not be detectable clinically.

In the zealous effort that accompanies the trial of various bronchographic media, it should be remembered that the instillation of foreign material into the respiratory tract represents a hazard to the patient, which is measured by the amount of irritative effect of the particular medium. Although the search for a more perfect medium should continue, caution must be exercised that good bronchographic detail is not achieved at the expense of increased risk to the patient.

Summary

Pathologic findings present after instillation of a water-soluble bronchographic medium into the right lung of four dogs reveal histologic findings of parenchymal fibrosis, six months after bronchography. It is suggested that this medium can exert a deleterious effect, even though there was no evidence of retention of it on roentgenographic, gross or microscopic examination of the lung.

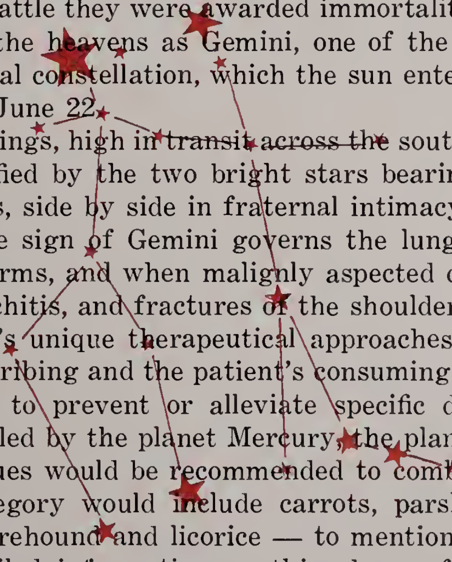
Astrology and Medicine — Gemini, The Twins



In Roman legend Castor and Pollux were brothers, notable for their skills — Castor in managing horses and Pollux in boxing. For distinguished military service in battle they were awarded immortality by Zeus, who had them translated to the heavens as Gemini, one of the three human signs and the third zodiacal constellation, which the sun enters about May 22 to remain until about June 22.

On February evenings, high in transit across the southern sky, the Twins can be easily identified by the two bright stars bearing their names and marking their heads, side by side in fraternal intimacy.

Astrologically, the sign of Gemini governs the lungs and bronchi, also the shoulders and arms, and when malignly aspected disposes to tuberculosis, pleurisy, bronchitis, and fractures of the shoulders, arms, and hands.

One of Astrology's unique therapeutical approaches to disease consists of the doctor's prescribing and the patient's consuming the planetary plant elements calculated to prevent or alleviate specific disorders. Since the sign of Gemini is ruled by the planet Mercury, the plant products endowed with Mercurial virtues would be recommended to combat Gemini morbidities. This food category would include carrots, parsley, caraway seeds, walnuts, filberts, horehound and licorice — to mention only a few.

For further detailed information on this phase of astrological therapeutics, the curious may consult Astrological Keywords by Manly Hall, The Hall Publishing Company, Los Angeles, 1929.

Cyclic Myositis

- *Dermatomyositis-*
- *Polymyositis*

DERMATOMYOSITIS IS a disease in which the involvement of the skin and muscles may last for years and which follows a variable course. The course has been described as acute, chronic, or recurrent. The acute, severe form and the chronic, debilitating form constitute almost all of the cases of this disease observed at the Mayo Clinic (Table 1). A third pattern referring to episodes that occur a year or more apart can be defined as the uncommon, recurrent form. We wish to report the particular qualities of a fourth pattern in myositis which has been observed since the use of corticosteroid therapy and which we call "cyclic myositis" or "cyclic dermatomyositis-polymyositis."

Cyclic myositis is characterized by recurrent exacerbations of myositis that follow clinical and laboratory evidence of remission induced by corticosteroids. The flare does not necessarily follow complete steroid withdrawal. In each instance repeated flares have resulted in steroid administration for years so that the course of clinical findings and steroid dosage is up and down like that of a roller coaster.

Case History

A 3½-year-old white boy with muscle weakness was brought to the Mayo Clinic. His birth and development had been normal. In April, 1956, he had had an episode of fever and coryza, and his parents had noted slowness in his running and walking. In the next two weeks there was regression to inability to climb stairs, raise the arms, or get onto a chair. There was never a complaint of pain or discomfort. The boy had been hospitalized with a diagnosis of Guillain-Barré syndrome. From June to October, 1956, improvement occurred with bed rest; the patient was more active, better co-ordinated, and able to use his arms enough to help with dishes and to handle toys. In the fall of 1956, two episodes of upper respiratory infection were accompanied by increased weakness progressing to almost total incapacity.

Examination in December, 1956, revealed marked weakness of the proximal muscles of the extremities. The boy walked with a waddling gait and was unable to climb onto a sofa or to rise from a recumbent

position. He could not hold his arms at shoulder level against gravity. The only cutaneous finding was a livid scaling area involving the middle of the forehead and both eyebrows.

Electromyographic examination of the left quadriceps femoris and left biceps brachii revealed fibrillation potentials in the resting muscles. During voluntary contraction, action potentials of the motor units were low in amplitude and consisted of spikes of short duration or polyphasic potentials with spikes of short duration. The proportion of polyphasic potentials was greater than that found in normal muscle. The mean duration of 30 action potentials in the biceps brachii was 3.9 milliseconds, about 60 per cent of the mean value for normal muscle measured by the same technic. The number of potentials relative to the strength of contraction was greater than normal. Conduction velocity of motor fibers of the ulnar, median, and peroneal nerves was normal, although the summated muscle action potentials evoked by stimulation of these nerves were greatly reduced in amplitude. The findings were compatible with myositis.

Biopsy of the left quadriceps muscle revealed that some muscle fibers were in various stages of degeneration and regeneration. These were scattered diffusely throughout the specimen. Increased variation in diameter of muscle fibers and a slight increase in amount of endomysial connective tissue were observed. Two small vessels were surrounded by lymphocytes and plasma cells. The abnormalities were consistent with a diagnosis of myositis. The value of serum transaminase was 535 units per milliliter (upper limit of normal is 86 units). Results of other laboratory studies at this time were normal.

Treatment and Course

Treatment was started with 60 mg. of hydrocortisone a day, and the value of serum glutamic oxalacetic transaminase decreased rapidly to normal. Administration of hydrocortisone was discontinued in July, 1957. At this time the boy had improved markedly; he could climb a ladder, but the quadriceps femoris and biceps brachii muscles were still weak, and he still had a minimal waddle in this gait.

Clinical Improvement Temporary

Monthly examinations showed clinical improvement, but in November, 1957, when the patient's strength was considered improved, serum transaminase was 12.1 μmoles per hour per milliliter (upper limit of normal is 1.43).

In December the mother informed us that the boy's weakness had returned and that he was unable to climb stairs. Treatment with hydrocortisone was started again with 60 mg. per day. Dosage was then changed to 12 mg. of triamcinolone (Aristocort) per day. On neurologic evaluation the muscles of the shoulder and the pelvic girdles were graded as 25 per cent of normal strength. Serum transaminase values decreased to within the normal range during the next five months, and the dosage of steroids was correspondingly decreased. In June, 1958, the patient had Cushing facies, hirsutism, and obesity of the trunk, but his muscle strength was considered normal. By October, 1958, the serum transaminase value had been normal for four months, the myositis was apparently arrested, and administration of steroid was stopped.

Clinical and Laboratory Remission

When the patient returned for a routine examination in January, 1959, he had been attending kindergarten every day. No increased weakness was noted on examination, but he seemed more irritable than usual. At this time his serum glutamic oxalacetic transaminase was 8.52 μmoles. For this reason he was given triamcinolone, 8 mg. per day. The serum transaminase value returned to normal during the next four months, and the hyperirritability disappeared. Muscle strength, which had been decreased in February and March after the administration of steroid was started, improved again with continued therapy. Improvement was concurrent with a decrease of serum glutamic oxalacetic transaminase (Fig.).

In September, 1959, the weight and height of the patient were normal for his age. He had not had any steroids for two months, and the serum transaminase value was slightly elevated to 2.04 μmoles. Two weeks later the transaminase value was 2.83 μmoles. An electromyogram showed improvement from 1956 but still revealed definite abnormalities. The patient was given 10 mg. of hydrocortisone four times a day. In October, 1959, he was improved clinically and was able to return to school. However, the serum transaminase value was 3.48 μmoles, and it continued to rise. Muscle strength appeared to be satisfactory for daily activities, but muscle testing revealed definite weakness in all proximal muscle groups of the extremities. By May, 1960, serum transaminase values were normal and the dosage of hydrocortisone was again decreased. In July, 1960, muscle strength was excellent, and muscle testing revealed good strength; the patient could climb without difficulty. The Cushing habitus had disappeared although residual striae were apparent.

The patient continued to take 20 mg. of hydrocortisone daily through the summer of 1960, but in November marked weakness was noted by the patients. The strength of the muscles of the shoulder and pelvic girdles, the deltoid and biceps brachii, and quadriceps femoris was estimated as 25 per cent of normal. The patient was irritable and was having night sweats. Serum transaminase value was 6.02 μmoles per hour per milliliter. The dose of hydrocortisone was increased to 40 mg. per day.

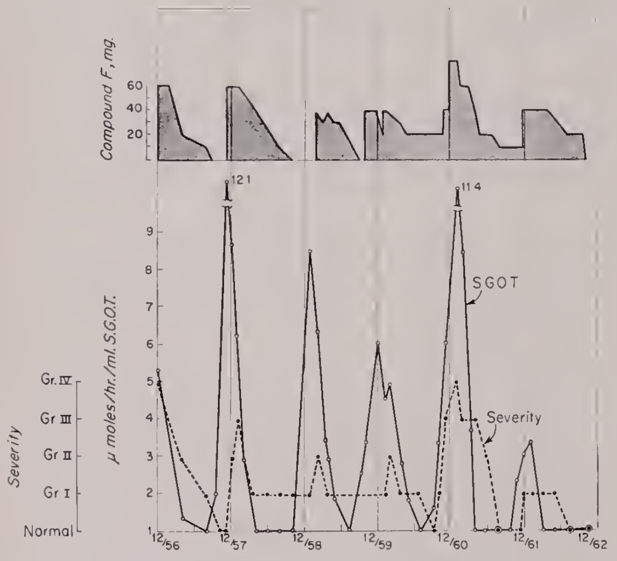

Fig. 1. — A comparison of results of hydrocortisone or triamcinolone treatment with the serum glutamic oxalacetic transaminase (SGOT) values in respect to time. SGOT and clinical course of myositis in relation to variations in dosage (intensity) of therapy with steroids, either hydrocortisone or triamcinolone. Note successive peaks of SGOT values and severity of myositis when steroid therapy was reduced.

Cyclic Pattern

In January, 1961, serum transaminase value was 11.4 μmoles (Fig.), and muscle strength had decreased. The parents stated that a relapse had occurred after rubeola earlier that month. The dose of hydrocortisone was increased to 80 mg. per 24 hours for one week, and serum transaminase values rapidly decreased. The night sweats diminished and irritability disappeared, but generalized muscle weakness could be demonstrated. No dysphagia was present. Therapy was changed to 12 mg. per day of triamcinolone (Aristocort) because of the availability of this drug.

By June, 1961, serum transaminase values were normal, and treatment was 1 mg. of triamcinolone four times a day. In July the patient's strength had improved and was almost normal. For the first time in one and one-half years the patient got up readily from the examining table and was able to climb without difficulty. Serum transaminase value was normal (.97 μmole) in August.

In September, 1961, the patient was receiving the same medication. He had had a cold, and his parents thought that a relapse was beginning because he had been falling oftener than usual. The serum transaminase value was slightly elevated (2.28 μmoles), but since clinical observers stated that the general condition was good, the administration of 1 mg. of triamcinolone twice a day was continued. The value of serum transaminase increased to 12.8 by the end of October, 1961; but the patient's strength at that time was recorded by his consultant as being good. During the next month his mother increased the administration of triamcinolone to 8 mg. per day because she considered his condition worse. Slight Cushing features developed, but by March, 1962, the serum transaminase value was again normal. The boy continued to receive 4 to 8 mg. of triamcinolone daily, and the serum transaminase values remained normal. He was asymptomatic, his strength was improved, and he could walk, climb, and attend school.

In February, 1963, serum transaminase value was slightly increased although muscle strength continued to be satisfactory. The patient was participating in recess activities at school against medical advice. Slight weakness of the muscles of the shoulder and the pelvic girdle was demonstrated on examination. The patient was continuing to take 4 mg. of triamcinolone per day. In July, 1963, electromyographic examination revealed more severe abnormalities than in 1959, but there was no specific evidence of increased muscular incapacity on clinical examination.

The Features of Cyclic Myositis

Nine patients of a study group of 290 patients (Cases 1 to 9, Table 2) with dermatomyositis-polymyositis demonstrated the oscillating course related to steroid therapy illustrated by Case 1. Each of the nine patients has been traced for four years or longer. At time of writing three are in remission after following this cyclic pattern, and six are classified as better although clinically, in most instances, they have continued to have recurrent episodes of muscle weakness accompanied by increased values of serum glutamic oxalacetic transaminase. We have not seen this course in patients who have not received steroids.

Onset of Symptoms

The duration of the illness at the time of diagnosis was less than one year in all cases, and in four it was less than six months. The disease began with cutaneous involvement in three cases, with cutaneous and muscular involvement together in one, and with the principal involvement in the muscles in five.

Of the nine patients, five were female and four were male. The four male patients were children. The age at onset varied from two to 59 years. Eight of the patients were postmenopausal women or prepubertal children, and the ninth was a 16-year-old girl with irregular scanty menses.

Cutaneous changes occurred in all of the patients at some time. Ulceration of the skin occurred in four and was related to calcinosis in two. Such ulcers healed slowly and often were associated with febrile episodes. Contractions were found in three patients. Sensitivity to sunlight was noted in two. Heliotrope-colored eyelids were observed in six, edema of the skin in three, and frank urticaria in one. The chronic, *symmetric erythema of* dermatomyositis was observed in five patients, and this proceeded to the development of poikiloderma in two. *Raynaud's phenomenon* was seen in three patients, two of whom also had sclerosis of the skin compatible with the diagnosis of sclerodermatomyositis.

Fever was a part of the early course in three patients; loss of weight was prominent in only one. *Muscle weakness* was the principal clinical phenomenon, and this weakness progressed until the patients were bedridden in three instances. *Dysphagia* was prominent in four patients, but esophageal roentgenograms showed that peristaltic action was absent in only one patient. Roentgenographic findings were normal in three patients. There was no major joint problem in any, although one patient had had rheumatoid arthritis five years previously.

TABLE 2
Nine Cases of Cyclic Dermatomyositis-Polymyositis

Case	Sex and age at onset, yr.	Duration of treatment, yr.	Number of cycles	Present status
1	M,2	7	5	Continued treatment in 1963
2	M,4	5	4	Remission
3	M,4	4	4	Remission
4	M,9	6	4	Continued treatment in 1963
5	F,16	9	4	Continued treatment in 1961
6	F,41	4	4	Continued treatment in 1960
7	F,46	5	6	Continued treatment in 1963
8	F.48	7	3	Remission in 1963
9	F,59	3	3	Continued treatment in 1963

Transaminase Level

Levels of serum glutamic oxalacetic transaminase were elevated in five patients. Otherwise, laboratory appraisal did not show consistent results. The L. E. cell test was positive in one. Basal metabolic rate was more than +10 per cent in four. The sedimentation rate was more than 10 mm. in one hour (Westergren) in seven of the nine cases, and the highest value was 52 mm. There was no correlation between the severity of the disease estimated clinically and the sedimentation rate. In one patient, the serum albumin-globulin ratio was reversed.

In all nine patients, the initial amounts of steroid that were received were more than 50 mg. per 24 hours.

Comment

Apparently, the cyclic course of myositis with steroid administration develops in a special type of patient. The patients in our series were female with the exception of four prepubertal males. Eight of the nine patients were not in the sexually mature era of life, being either children or postmenopausal women. The only other notation in the literature relating dermatomyositis to sex is that of Muller and associates[1] who found that calcinosis developed in a greater proportion of females than males.

The myositis from which these patients suffered was severe. It had come on rather acutely in all patients and had produced grade 4 muscular incapacity during some stage. Contractures, disability, and calcinosis were frequent in this group despite the administration of steroid. The skin was involved to some extent in all cases, and the entire range of types of cutaneous involvement in dermatomyositis was displayed. Sensitivity to sunlight, erythema, edema, poikiloderma, Raynaud's phenomenon, and sclerosis were all seen in these patients.

One characteristic of cyclic myositis is its prolonged course. All of the patients have had their myopathy a minimum of three years, and the disease continues in the majority of these patients. While the administration of steroid brings symptomatic and objective relief, it does not shorten the course.

Speculation as to why this cyclic form of myositis occurred may begin with the fact that those who developed this course were a special group of prepubertal or postmenopausal female or prepubertal male patients with acute myositis who were early given a high dosage of steroids. None of the patients who had chronic myopathy and who were given steroid therapy demonstrated this course. Steroid suppression of the symptoms of the disease may also suppress the capacity of the body to resist this type of muscle inflammation and degeneration. Although the symptoms are suppressed, the disease remains. Therefore, with withdrawal of the medication, the pathologic process reasserts itself. In Case 1 it was not necssary to discontinue administration of steroids in order for a flare of the process to occur. In fact, the last flares occurred even though a maintenance dose of steroid, which had appeared adequate on previous occasions, was continued.

Complications of Steroid Therapy

Complications of steroid therapy were minimal in our nine patients. Cushing facies, hirsutism, and redistribution of body fat were common, but otherwise no serious complications were encountered although steroid was used for as long as nine years in some of these patients. The dose would be considered high as conservatively defined by Mulder and associates.[2]

Physical activity may affect the course of illness in these patients. In our Case 1, flares occurred in the fall of the year when the patient returned to school and to more active participation in school activities. Many of the patients had annual flares. Flares of the myopathy have occurred in symptomatically well-controlled patients after active participation in work or play or in carrying out strenuous physical therapeutic programs. For several of our patients who had cyclic myopathy, assiduous attention to physical exercise was a feature of the home program. It seems likely that the flares that occurred when the patients were taking only small doses of steroid possibly were induced by excessive physical work of an involved muscle.

Successful treatment of dermatomyositis or polymyositis seems to require the balance of (1) appropriate steroid therapy, (2) nutrition to overcome the negative nitrogen balance that is common, and (3) mild physical exercise that is calculated not to aggravate the disease process in the muscle but that is adequate to maintain a normal physical range of motion and to prevent the development of contractures of muscles and tendons.

Summary

In the nine cases of cyclic dermatomyositis-polymyositis studied, a chronic up-and-down course in dermatomyositis-polymyositis appeared to be related to steroid therapy and has been observed only in patients treated with corticosteroids. Prolonged therapy with steroid may not produce remission of the disease although signs and symptoms are suppressed. In such patients steroid withdrawal is accompanied by a flare of myositis. Because flares of the disease process occur in a cyclic manner, often in relation to physical exercise and despite continuance of maintenance doses of steroid, the appropriate therapy of myositis is thought to depend on the balance of steroid therapy, nutrition, and physical activity.

Primate — Homo Sapiens

Australopithecus

If you will go to the bathroom, lock the door, and observe yourself closely with neither shame nor pretension, you will discover yourself in the presence of a mammal so primitive and so generalized as to be difficult to describe. You have no distinctive horns arranged like a musical instrument on top of your head. Nobody would dream of shooting you for your tusks. Your hide is worthless, your vestigial fur of comic proportions. No intricate patterns adorn your surface; it has neither the camouflage value to make possible your vanishing into a landscape, nor such decorative value as to warrant your being nailed to a wall. Your teeth lack any special superiority, either for munching hay, chiselling through doors, or penetrating jugular veins. Your claws are so inadequate that while a kitten may scratch you, you cannot scratch the kitten back. And while it is true that you are warm-blooded, and that you do not lay eggs, and that you are edible, still the same may be said of all other mammals. How any creature could survive at least one hundred million years of mammalian evolution and acquire as few specializations as yourself is the chief wonder with which you might attract the attention of a zoologist visiting from another planet. — Robert Ardrey: African Genesis, Atheneum Press, N. Y., 1961.

Violence in the voice is usually the death-rattle of reason. — Arkansas Methodist

WHAT'S YOUR DIAGNOSIS?

A lady, age 72, was admitted October 2, 1964, with a history of five days of intermittent abdominal pain and vomiting, progressing to more steady abdominal pain and profuse vomiting.

There had been intermittent similar episodes of a more mild degree since April 1964. In that month because of these complaints colon and stomach X rays were done and were negative.

The patient had long-standing moderate hypertension, with a more severe elevation occurring in January 1964. Treatment consisted of attempted weight reduction and Esidrix-K, this medication being discontinued in June 1964 and no other medication given. A more remote past history related a cholecystectomy for stones in September 1942; epigastric distress in March 1944, treated with antacids which brought relief, and a gastrointestinal X ray which failed to reveal any ulceration or other abnormalities; curettage in May 1948, which revealed carcinoma of the body of the uterus, followed by a panhysterectomy preceded by X ray therapy; in September 1950, fulguration of an irradiation ulcer within the bladder, followed by healing; in 1958, examination essentially negative in a study of intermittent diarrhea, probably related to prior X ray therapy. That problem subsided without specific therapy.

Physical examination on this admission revealed blood pressure of 160/90, 190/100, 180/108. Pulse 70— regular. Weight 185. Abdominal distention with borborygmi present, no tenderness, distention moderate at 2+; rushes of bowel sounds occurring every two to three minutes with normal sounds in the intervals, and colic associated with peristaltic rushes. Pelvic examination revealed vaginal-wall constriction, no masses.

X ray revealed a moderate amount of small-bowel gas and some in the colon, with small-bowel fluid levels in the upright position.

The findings were suggestive of inhibitory ileus, but partial obstruction of the small bowel could not be ruled out.

Laboratory work: Hemoglobin 14.3; WBC 6,125 with 73% PMN'S; Amylase 23; BUN 11; CO_2 31.4; Chloride 97.5; Sodium 139; K 4.1.

ITS THE LAW

Failure to Refer Patient to Specialist Constituted Negligence

In an action by a patient against a doctor for damages for his alleged negligence in setting the four-year-old patient's elbow fracture in a closed reduction, there was evidence from which a jury could find that the doctor was negligent in failing to refer the patient to an orthopedic specialist and that this was the proximate cause of the patient's injury, the Michigan Supreme Court ruled. There was also damage to the epiphysis of the elbow. When the patient continued to have trouble with the arm, an orthopedic surgeon performed several corrective operations. A general practitioner who testified for the patient stated that the doctor violated the standard of practice in the same or similar localities by failing to refer the patient to an orthopedic specialist who, in his opinion, would have discovered the damage to the epiphysis of the elbow at the outset and would have set the fracture by open reduction and the insertion of noncorrosive pins.

The orthopedic specialist who performed the corrective surgery testified that he could see the epiphyseal injury on the original X rays taken by the doctor. This was evidence from which a jury could find that, if the patient had been referred to an orthopedic specialist immediately, his arm would not have been permanently and painfully injured, the court ruled.

Morgan v. Engles, 127 N. W. 2d 382 (Mich., Apr. 6, 1964)

Cirrhosis of the Liver in Pregnancy

*A Case Report and Review of the Literature**

C. A. SHATTUCK, M.D. **
W. N. SPELLACY, M.D.**
Minneapolis, Minnesota

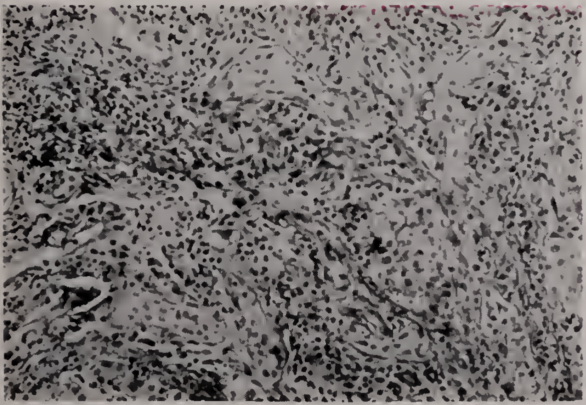

Fig. 1 — Liver biopsy.

THE OCCURRENCE of pregnancy in a patient with cirrhosis of the liver is rare, there being only 35 cases reported. The reason for this infrequent association seems to be the secondary amenorrhea with infertility produced by this debilitating disease.[1] The purpose of this paper is to present the 36th case and to review the literature.

Case Report

A 33-year-old white female was admitted to the University of Minnesota Hospitals on January 30, 1964, for the second time. Her pertinent medical history dates back to 1954 when she had a cholecystectomy performed, which was complicated by a postoperative biliary stricture. An unsuccessful attempt at surgical repair was made at that time. From 1954 to 1956 the patient had recurrent episodes of chills, fever, abdominal pain, and jaundice. Abnormal liver function studies were found which included a total serum bilirubin of 5 mgm.%, cephalin flocculation of four plus, and an alkaline phosphatase of 27 King-Armstrong units. In 1956 a choledochojejunostomy was performed with only partial relief of symptoms. This operation was redone in 1957. The liver at that time was described as being "enlarged, firm and nodular." *A biopsy was performed which showed scarring compatible with the diagnosis of cirrhosis* (Figure 1). From 1957 to 1963 the patient did well, had minimal pain and normal liver function tests. She has never experienced gastrointestinal bleeding.

The patient's obstetrical history included three uncomplicated term deliveries prior to 1954. In 1959 at 30-weeks gestation the patient was referred to the University of Minnesota Hospitals for evaluation. The liver function studies at that time are shown on Table 1. Of note are the reversed A/g ratio, elevated cephalin cholesterol flocculation test, increased thymol turbidity, and an increased brom sulph phthalein retention.

In 1961 the patient had a spontaneous abortion at 20-weeks gestation, cause unknown. The pregnancy did not alter her liver-function studies. At 38-weeks gestation the patient was referred to the University Hospitals on February 14, 1964. Her course had been uncomplicated until three weeks prior to her admission when she developed anasarca and hydramnios, with an associated increase in right upper quadrant abdominal pain and jaundice. The patient's fluid retention was unchanged by treatment with low salt diet, bed rest and thiazide diuretics.

The physical examination showed a jaundiced patient with edema, ascites, and hydramnios. The temperature and blood pressure were normal; the fetal heart tones were normal. The admission laboratory results are shown on Table 1. At that time the laboratory tests showed normal cephalin cholesterol flocculation and thymol turbidity, but there was an elevated bilirubin, brom sulph phthalein retention, and alkaline phosphatase. The total protein concentration was lower with a persistent reversal of the A G ratio.

---

*Presented at the Minnesota State Obstetric and Gynecologic Society Meeting, May 9, 1964, at Rochester, Minnesota.

**Dept. of Obstetrics and Gynecology, University of Minnesota Hospitals.

It was apparent that the fluid retention was due to a decreased plasma colloidal osmotic pressure. The patient was treated with intravenous plasma and salt-free albumin. She also received a one-gram-per-day sodium diet, bed rest, and diuretics. A rapid diuresis was produced. On February 16, she spontaneously began labor, and after a total labor of two hours and 47 minutes she spontaneously delivered a 2600-gram normal female infant which survived. The umbilical cord bilirubin and serum proteins with A/G ratio were normal. The patient's massive diuresis in the first seven hospital days and the removal of the pregnancy decreased her weight by 38 pounds. She was discharged from the hospital on the 12th post-partum day and has done well subsequently. Her liver function was studied nine weeks post partum and is shown on Table 1. Of note are the elevated cephalin cholesterol flocculation test and increased thymol turbidity.

TABLE I

Liver Function Studies

Test	1959	1/30/64	Postpartum
Hbg. (gm. %)	11.5	12.1	11.3
W.B.C. (cell/mm.^{3})	4,700	5,550	6,100
Electrolytes (meq/l)	not done	normal	normal
B.U.N. (mgm. %)	not done	7	11
Serum bilirubin (mgm. %)			
one minute	0.4	2.1	0.4
total	1.0	3.8	0.8
Prothrombin time (seconds)			
patient	13.5	11.7	11.5
control	12.6	11.5	12.0
Cephalin-cholesterol	3+	negative	2+
Thymol turbidity	7	2	8
Total serum proteins (gm. %)	6.7	5.7	7.2
Albumin	2.6	2.0	3.4
Globulin	4.1	3.7	3.8
Alk. phosphatase (K.A. units %)	11.3	26	9
B.S.P. (% retention 45 minutes)	24	28	not done

Discussion

In 1957 Abrams found 15 reported cases of cirrhosis of the liver and pregnancy in the English literature and added two of his own. Since that time 18 additional cases have been reported, bringing the total to 35.

Of the 35 cases, 24 were delivered vaginally. There were five maternal deaths. In no case was the pregnancy considered to decrease the liver reserve. Bleeding from esophageal varices is an important cause of maternal death and both splenorenal and portacaval shunt operations have been done during pregnancy.[12,14,16,17] There is no change in the expected outcome of the liver disease due to pregnancy.

Five fetal deaths have been reported. In two cases the mother died undelivered; a third infant had a congenital abnormality incompatible with survival; a fourth infant died of intracranial hemorrhage; the fifth case was a stillborn of unknown cause. The fetal outcome in one case is not reported. The corrected fetal mortality is not increased.

Many studies have been reported of the normal variations in liver function tests during pregnancy. All of the tests remain normal in the first trimester. At term the brom sulph phthalein, cephalin cholesterol flocculation, thymol turbidity and bilirubin remain normal. There is a progressive elevation of the serum cholesterol and alkaline phosphatase levels during the second and third trimesters, also a decreased serum protein concentration, principally due to an albumin decrease.[19-22]

The present case is interesting in that the liver function tests deteriorated during pregnancy. Since exogenous estrogens can cause an exacerbation of liver disease it has been postulated that pregnancy will do the same.[1] Perhaps this is a case in point. This patient's main problem was fluid retention due to her low plasma protein concentration. The proteins are mainly produced by the liver. Their production capacity was probably limited before pregnancy and with the superimposed "pregnancy-albumin-decrease" a critically low colloidal osmotic pressure developed and fluid retention occurred. This readily responded to exogenous albumin.

The advocated mode of delivery is by the vaginal route unless gastrointestinal bleeding is a problem. With bleeding varices cesarean section is recommended.[16]

Conclusion

Cirrhosis of the liver is an uncommon complication of pregnancy. Generally, the disease does not adversely affect the pregnancy nor does the pregnancy adversely affect the disease. The 36th case is reported and the literature is reviewed.

Pliny's* Cure for Toothache

Pliny recommended the ashes of deer's horns to strengthen loose teeth or allay toothache. This was used either as a friction or as a gargle. He indicated that some people, however, are of the opinion that the horn, unburnt and reduced to powder, is still more efficacious. The hare's rennet is sometimes injected into the ear for this purpose; and the pastern-bone of an ox, ignited and applied to a loose tooth with ashes, has the effect of tightening the teeth in their sockets. When the teeth have been loosened by a blow, they are strengthened by applying asses' milk or else the ashes of the burnt teeth of that animal, or a horse's lichen, reduced to powder and injected into the ear with oil. In referring to the lichen of the horse, Pliny speaks of the excrescence which forms upon the knees of horses just above the hoofs. He mentions that in the heart of the horse there is found a bone** which bears a close resemblance to the eye-tooth of a dog; if the gums are scarified with this bone, or with a tooth taken from the jawbone of a dead horse, corresponding to the place of the affected tooth, the pain will be removed.

Another remedy for diseases of the teeth is joiner's glue, boiled in water and applied, with care being taken to remove it very speedily and instantly to rinse the teeth with wine in which sweet pomegranate rind*** has been boiled. It has also been considered very efficacious to wash the teeth with goats' milk or bull's gall.

---

*See Minnesota Medicine June, 1964, Page 716.

**Os cordis in the horse but more prominent in the heart of a cow is found in the aortic ring. In the younger animal it is cartilagenous.

***Pomegranate rind — astringent.

We live for it, if need be we die for it. We mortgage our future to keep it alive. Some day we hope to agree on what it is. — Senator Soaper

Drugs in Pregnancy*

A warning to all from a world authority: Avoid unnecessary medication during pregnancy.

FRANCES O. KELSEY, Ph.D., M.D.**
Washington, D. C.

THE RECOGNITION in late 1961 of the teratogenic*** effect of thalidomide in man has led to widespread efforts to determine whether other drugs administered during pregnancy may play a contributory role in causing congenital malformations. However, even before the thalidomide episode increasing attention had been directed toward the question of safety of drugs during pregnancy, largely because of the recognition through animal studies and clinical observations that the embryo and the newborn are unable to metabolize many drugs as effectively as the adult. The present paper will review current information concerning the effect on the fetus of drugs administered to the mother during pregnancy and discuss possible means of reducing such drug-induced injury.

Incidence of Malformations

The incidence of congenital malformations has been variously reported as ranging from less than 1 per cent to 8 per cent. Additionally, malformation has been said to occur in some 20 per cent of stillbirths and in a substantial but unknown number of abortions. It is difficult to arrive at a precise estimate of the total number of malformations or the incidence of any given malformation. Observers may vary in their criteria for congenital malformations or in their ability to recognize them. Furthermore, perhaps 50 per cent of congenital malformations are not recognizable at birth. Such factors contribute to the unreliability of data provided from birth certificates. Additionally, eight of the 56 reporting areas for vital statistics do not require the recording of congenital malformations on birth certificates while three do not require a description of the malformation.

Etiology of Malformations

Approximately 10 per cent of human congenital abnormalities are associated with known genetic factors, and a few, perhaps 1 per cent, with known *environmental factors* such as irradiation, German measles, and certain drugs. At present, however, in the vast majority of cases no definite etiology has been established. It is of considerable interest and importance, therefore, to determine what role drugs or other environmental factors may play in producing such deformities, either singly or in combination or conjunction with genetic factors.

Effect of Drugs During Early Differentiation

Animal experiments have indicated that a wide variety of drugs may cause congenital malformations or death in the young if given during a critical time during pregnancy. There is little evidence of drug-induced malformations occurring following exposure of the embryo during the predifferentiation period, when the cells still retain their totipotency.* The state of early differentiation appears to be the period of highest susceptibility for congenital malformations. *In man, this extends from about the tenth to about the fiftieth day after conception.* As the various organs and systems become increasingly differentiated, they become less susceptible to teratogenic agents. In all periods, however, the adverse effects of the drug may lead to death of the embryo.

X-irradiation

The first environmental factor to be linked with the production of congenital defects in human beings was x-irradiation. Murphy, in 1928, reported that microcephaly and mental retardation occurred with a high degree of frequency in the offspring of mothers who received x-irradiation to the pelvis during pregnancy. Similar malformations were described in offspring born to mothers who during their early pregnancy were exposed to the atomic bomb exploded in Hiroshima in 1945.

German Measles

In 1941, Gregg in Australia first recognized that German measles in the first trimester of pregnancy was frequently associated with severe congenital malformations in the offspring. The defects most commonly noted are malformations of the heart and of the eye, and microcephaly.

Aminopterin

The teratogenic effect of the folic acid antagonist, aminopterin, was first recognized in 1952 when this agent was used as a therapeutic abortifacient. In 24 pregnant women receiving the drug, four cases of congenital malformations were noted in the eight cases that required surgical intervention because spontaneous abortion did not occur. Defects included central nervous system damage and cleft palate.

Alkylating Agents

Congenital malformations have been reported in children born to mothers with Hodgkin's disease, who were treated with the alkylating agents cyclophosphamide and chlorambucil, respectively, during pregnancy, and in a child whose mother received a combination of busulfan and mercaptopurine during pregnancy for the treatment of chronic myelogenous leukemia. Fetal abnormalities have been produced in animals with a variety of antineoplastic agents administered during pregnancy.

Progestational Substances

The teratogenic effect of certain progestational substances and other steroids advocated for the control of bleeding in pregnancy, or for the treatment of threatened abortion, was first described in 1958. Such drugs given during the first trimester of pregnancy led in a small per cent of cases to masculinization of the external genitalia in the female fetus. Evidence available at this time suggests that the defect carries no functional disabilities, but the condition must be differentiated from the more serious but anatomically similar virilizing adrenal hyperplasia. Finally, the potent teratogenic effect of thalidomide was first reported in late 1961 almost simultaneously by McLeod in Australia and Lenz in Germany.

Thalidomide

The characteristic malformations were limb defects varying from the shortening of a single bone to complete absence of all the long bones of the extremities. Most frequently affected were the upper limbs. Other deformities included absence or deformity of the external ear, absence of the internal ear with deafness, a characteristic birthmark over the forehead and, less frequently, congenital heart disease and intestinal stenosis. Dr. McBride reported that in a series of 40 women receiving thalidomide during the first trimester of pregnancy, 14 (or 35 per cent) delivered babies with deformities now known to be characteristic of thalidomide ingestion.

---

*See Test Your Word Score Page 211.

Oral Hypoglycemic Agents

In addition to those drugs which have been clearly implicated in fetal malformations, a number of preparations have been suspected of being teratogens either on the basis of animal studies or on the grounds of somewhat limited clinical observations. For example, tolbutamide has produced congenital malformations in certain animal species, while in one clinical study the use of chlorpropamide was associated with a high perinatal mortality and one case of microcephaly.

While diabetes mellitus itself may predispose to fetal malformations, nevertheless, these findings have led to a questioning of the safety of these oral hypoglycemic agencies in pregnancy. Additionally, clinical experience indicates that, generally speaking, pregnant diabetics are better controlled with insulin than with oral hypoglycemic agents.

Antihistamine Preparations

Two antihistamine preparations, meclizine and cyclizine, have been shown to be teratogenic in some species of animals; and certain clinical studies, but not all, have suggested that such drugs may occasionally have a teratogenic effect in human beings. Again, evidence is hard to establish because of the widespread use of such agents to control nausea and vomiting of early pregnancy and the fact that there may be a somewhat higher incidence of malformations in patients who suffer from the nausea and vomiting of pregnancy. The evidence, however, does suggest that alternate measures of controlling nausea and vomiting should be considered.

The Developmental Stage of Embryo

Although only a few agents have been definitely associated with congenital defects in humans, nevertheless, certain principles established in animal studies appear to apply also to drug-induced teratogenesis in human subjects. In the first place the susceptibility of the embryo depends on the developmental stage at which the agent is applied, as does to some extent the nature and extent of the defect produced. Furthermore, whereas there may be a certain degree of overlapping in the effects evoked by the various teratogenic agents, each agent appears to elicit characteristic effects. Again, the experience with aminopterin illustrates that a drug capable of causing death to the fetus may also lead to congenital malformations under certain circumstances. Finally, the experience with thalidomide demonstrates that a drug can produce profound effects in the embryo without affecting the well-being of the mother.

Ineffective Placental Barrier

Until comparatively recently, it was assumed that the placenta formed an effective barrier to protect the fetus from the passage of drugs and other agents from the maternal circulation to the fetal circulation. It is now recognized, however, that the transfer of substances across the placental barrier is governed primarily by the same physical and chemical laws that determine the transfer of substances across all cell walls.

Effect of Low Lipoid Solubility of the Drug

The chemical nature of cell walls is such that nonionized drugs with high fat solubility are transferred rapidly, while drugs with high degrees of dissociation or of low lipoid solubility either cannot be transferred or are transferred in small amounts only. Additionally, very large molecules or substances bound to plasma proteins may fail to pass the barrier. Similar principles apply to the handling of drugs by the gastrointestinal tract, the passage of drugs through the so-called "blood-brain" barrier, and the localization of drugs in certain tissues or organs.

Pathologic Changes in Placenta

Once the drug has passed the placenta its effect on the fetus will depend on a number of factors, such as the ability of the fetal tissues to metabolize or detoxify the compound, the disposition of the drug or its metabolites in the tissue of the fetus, and the susceptibility of the fetal tissue to the adverse effects of the drug. Additionally, the permeability of the placenta may well be altered by such factors as pathological changes in the placenta, changes in maternal and fetal blood flow of the placenta, and maternal infection, dehydration or hemorrhage.

Metabolic Processes in the Mother

It should be borne in mind that the effect of drugs on the fetus need not necessarily be a direct one. Animal experiments indicate certain drugs may affect the fetus indirectly by interfering with metabolic processes in the mother.

Hyperthyroidism

Drugs that freely pass the placental barrier may elicit pharmacologic and toxic effects on the fetus or newborn similar to those observed during therapy with the drug. Thus, thiouracil derivatives or iodides given to the mother during pregnancy for the treatment of hyperthyroidism or iodides given for asthma may lead to congenital goiter, which may be accompanied by a hyperthyroid, hypothyroid or euthyroid state. Such goiters usually regress spontaneously after delivery when the influence of the drug is no longer present. However, they may be sufficiently large to interfere with normal delivery or to offer mechanical respiratory obstruction after birth, which may require surgical intervention.

Anticoagulants

Anticoagulants administered for the treatment of thrombophlebitis during pregnancy may result in fetal or neonatal hemorrhage and death.

Babies born to *morphine addicts* may have pin-point pupils at birth and may suffer from severe and even fatal withdrawal symptoms; while babies born to mothers receiving *reserpine* may have a characteristic syndrome of stuffy nose and respiratory distress. Large doses of *quinine during pregnancy* have been reported to result in fetal deafness, and 8th nerve toxicity has also been reported for streptomycin.

Growth Retardation in Bone and Teeth

A recently observed adverse reaction to a drug given during pregnancy is that of the staining of deciduous teeth in children whose mothers received a *tetracycline* drug during the last trimester of pregnancy. A similar effect is seen in the deciduous teeth of infants receiving the drug or in the permanent teeth of children receiving the drug from the third up to the sixth or seventh year of life. Apparently tetracyclines have a predilection for bones and the developing tooth. Animal studies indicate they are deposited in the growing bone and may result in some growth retardation that is reversible after discontinuation of the drug. A similar effect has been noted in premature infants.

Fetal Tissues Lack Detoxifying Enzymes

In recent years, it has become apparent that the fetus and newborn may react in a unique fashion to certain drugs. In many instances, this is because the fetal tissues lack many of the enzymes necessary for the detoxification of certain drugs. Additionally, the immature kidney is unable to excrete drugs as rapidly or effectively as the adult.

The "Grey Syndrome"

Sutherland reported that the susceptibility of newborn infants, particularly premature infants, to chloramphenicol was due to the inability of the liver to form the less toxic glucuronide. The resultant high blood level of chloramphenicol leads to cardiovascular collapse, the so-called "grey syndrome." Again, the administration of certain drugs, such as long-acting sulfonamides, novobiocin, and water-soluble Vitamin K may affect the metabolism of bilirubin and lead to hyperbilirubinemia with an increased risk of kernicterus and death. A number of factors appear to be involved. Thus, drugs may compete with bilirubin for the inadequate hepatic enzymes that ordinarily conjugate bilirubin to the less toxic glucuronide.

Destruction of Hemoglobin

The red blood cell of the fetus and the newborn has an enzyme deficiency which predisposes it to hemolysis by various drugs including water-soluble Vitamin K preparations. The increased bilirubin from the destruction of hemoglobin will tax further the inadequate detoxification mechanisms of the immature liver. Additionally, drugs may compete with bilirubin for binding sites on plasma albumin, leading to an increase in free (or toxic) bilirubin.

The recognition of the role of water-soluble Vitamin K preparations in jaundice of the newborn has led to recommendations that when these substances are given to the premature infant in hemolytic disease of the newborn, the maximal daily dose should not exceed 1 milligram. Furthermore, since the safety and effectiveness of administering these preparations to mothers in pregnancy for the prevention of hemorrhagic disease of the newborn has not been established, it is recommended that these preparations be given to the infant after birth rather than prenatally through the mother.

Discussion

It is recognized that tests may well fail to be of any predictive value in regard to the behavior of a drug in pregnancy in human subjects. Many widely used drugs may exhibit effects in one or more species of animals if taken during pregnancy but have not been established as causing adverse effects in man. Alternately, thalidomide fails to exert the same striking teratogenic effect in certain animal species that it does in man and certain other species of animals. However, data on the effect of most drugs on pregnancy in either animals or man are admittedly quite fragmentary. As more data are accumulated, more appropriate screening procedures may be devised.

The procedure presently recommended by the FDA consists essentially of feeding subtoxic doses of the drug under test to male and female rats, for a preliminary period of six weeks and then through two pregnancies. It should be emphasized that this test is intended not only to detect drugs that may cause teratogenic effects but also those which may effect spermatogenesis or fertilization or implantation, or otherwise adversely affect the rat fetus or welfare of the newborn.

Thalidomide tested by this procedure produces few if any fetal abnormalities but causes a significant reduction in litter size. Tested in certain strains of rabbits, another species commonly employed in teratologic screening procedures, it causes fetal malformations not unlike those produced in human subjects.

If preliminary screening tests indicate an adverse effect on the fetus, further animal species should be studied and more information made available concerning such factors as absorption, metabolism, and excretion of the drug in animals and in man. The question as to whether a drug which shows an adverse effect in animal species during pregnancy should be tested in women of the childbearing age may be a difficult one to resolve. In cases of drugs used in life-threatening conditions the use of such drugs in pregnancy may well be justifiable. It is doubtful, however, whether similar risks should be taken for a drug such as a mild sedative or a hypnotic for which there are other preparations available.

Failure to elicit teratogenic effects in animals offers no assurance that the drug can be safely used during human pregnancy. In all cases where new drugs are used in pregnant women, very accurate records should be taken of the time of administration, the amount of drugs given and the duration of therapy. Furthermore, the child should be carefully examined at birth and carefully followed at least through the first year of life.

The report by McLeod indicates that a well-controlled prospective study could readily have demonstrated the adverse effects of thalidomide before it caused such widespread damage, since it produced a high incidence of malformations of a conspicuous nature.

Additionally, if drugs are to be used in infants, it should be required that the LD_{50} be determined in the day-old rat, with the hope that it may be possible to detect any abnormal pattern of detoxification in the newborn. Data submitted indicate that the acute toxicity of certain drugs may vary widely if tested in the newborn and the adult animal. Again, recommendations for pediatric use of a drug must be substantiated by adequate clinical studies to establish the safety and effectiveness of the drug in the appropriate age group or groups.

Conclusion

It is recognized that the growing awareness of the adverse effects of certain drugs on the fetus and newborn presents many practical problems to the physician. With more careful clinical studies and further basic research more definite guidelines may be available for the safe use of drugs during pregnancy.

Unnecessary medication during pregnancy is certainly to be avoided, and in particular women of the childbearing age should be counselled against self-medication.

It must be recognized, however, that some conditions in the mother, if left untreated, may well predispose to adverse effects in the offspring, while others may be so threatening to the life of the mother that it would be unjustifiable to withhold an effective drug for fear of possible teratogenesis.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 170)

The patient was operated on within the first 24 hours after admission. Findings revealed two small narrow areas of constriction in the terminal ileum approximately 24 inches from the ileocecal valve. The area of most marked constriction was 6" distal to one of lesser constriction. All of the remainder of the bowel was of normal color and texture. There were no adhesions by or proximal to the constriction. Slight to moderate distention. Pelvis free of tumor. Periaortic area all normal.

A resection of the involved area and primary anastomosis was accomplished. The patient recovered and was discharged the ninth postoperative day, having an uneventful convalescence.

Pathology: Submucosal fibrosis, marked in 1 cm. area with 3 mm. ulcer on one side of the mucosa, considered to have been caused by enteric-coated Esidrix K which was discontinued in June 1964 because of abdominal distress.

Not only is nature useless, it may even be harmful. A natural healing power, curing diseases by design, is a delusion. The physician must actively interfere with nature. It is the physician's duty to cure safely, quickly, pleasantly: tuto, cito et jacunde.

Hemobilia Due to Common Duct. Hepatic Artery Communication Following Operations on the Biliary Tract*

KAREL B. ABSOLON, M.D.**
LUIS F. URDANETA, M.D.**
PATRICK HAGIHARA, M.D.**
RICHARD L. VARCO, M.D.**
Minneapolis, Minnesota

HEMOBILIA, a term coined by Sandblom of Sweden, designates hemorrhage via the common duct into the duodenum.[14] The most common cause is trauma resulting in a capsular or subcapsular hepatic tear, as originally described by Owen.[12,15] Massive and recurrent hemobilia may also be associated with penetrating hepatic injuries and such conditions as ruptures of hepatic artery aneurysms into the common duct and hemorrhagic cholecystitis.[4,6,10] Bleeding due to ductal wall erosion by a T-tube or a stone was described previously.[13]

The occurrence of hemobilia following common-duct surgery is a rare cause of massive upper gastrointestinal hemorrhage; only occasional reports are listed in the world literature.[2,7] As iatrogenic complications, such cases are not readily reported by the operating surgeon. Several extensive reviews on complications of cholecystectomy do not mention hemobilia.[1,5,11] Kehr referred to erosion of the portal vein and hepatic artery by a common-duct stone.[8] Even though the causes of hemobilia were carefully classified by Kerr and Lichtman, massive hemobilia as an iatrogenic sequela of surgery on the biliary tract was not listed.[9,10] Furthermore, hemobilia was not observed as a complication of biliary surgery in patients operated on at the University of Minnesota Hospitals.

Patients with hemobilia secondary to biliary tract surgery present symptoms similar to those discussed by Sandblom.[14] The inciting trauma differs from cases due to liver injury and may be paraphrased by the referring physician as "difficulty of identifying portal structures associated with bleeding." Pain simulating biliary colic may be followed by gastrointestinal hemorrhage; jaundice may be due to obstructing clots in the common duct or concomitant operative injury to

**From the Department of Surgery, University of Minnesota, Minneapolis, Minnesota.

the common duct. Accurate preoperative diagnosis is a common problem, and an operative solution may be challenging to both the patient and the surgeon.

In all three patients in this report a cholecystectomy and a common-duct procedure were performed prior to admission to the University of Minnesota Hospitals. In one patient, in addition to a cholecystectomy, the first operation consisted of a Billroth II type gastrectomy for gastric ulcer. In the other patients recurrent episodes of upper gastrointestinal hemorrhage were observed, but no other gastrointestinal pathology was demonstrated with barium contrast. The cause of bleeding was established with certainty only at time of surgery. In one case gastrointestinal hemorrhage was accompanied by bleeding from the T-tube tract.

Despite the difficulties encountered in dissection of the portal area, anatomical relationships could be established in all three patients. Hemorrhage was arrested by ligature of the offending vessel or reconstruction of the bleeding artery, and a successful outcome obtained in two patients. In the third patient the outcome was predetermined by poor liver function due to biliary cirrhosis secondary to a concomitant development of postoperative biliary-duct stricture. An attempt at reconstruction of the hepatic artery with a patch of Teflon and choledoduodenostomy terminated fatally, due to disruption of both repairs. Exsanguinating hemorrhage and bile peritonitis were the terminal events.

Case Reports

Case No. 1

This 56-year-old white female had suffered for some years with right upper quadrant pain diagnosed as chronic cholecystitis and cholelithiasis. On 8/26/63 the patient underwent a cholecystectomy in an outside hospital, at which time the common duct was inadvertently severed and the structure repaired by direct end-to-end anastomosis over a T-tube. On 9/5/63 an episode of bleeding was noted via the T-tube, which became obstructed with clots. The patient received vitamin K and five units of whole blood. Approximately one week later more bleeding was noted around the T-tube. A T-tube cholangiogram was normal. Dark, bloody, liquid stools were noted, and the patient received five more units of whole blood as replacement. An upper gastrointestinal series was within normal limits, with suggestion of questionable compression of the first part of the duodenum. After an essentially asymptomatic interval of three weeks the patient was readmitted to the hospital because of hematemesis and tarry stools, requiring 12 units of blood for replacement. On 10/15/63 she again had to be transfused with 3½ units of blood for gastrointestinal bleeding. On 10/21/63 she complained of epigastric fullness and showed further evidence of upper gastrointestinal hemorrhage. At this stage of her illness she was transferred to the University of Minnesota Hospitals.

The past history of this patient was not contributory, with the exception of dysuria caused by interstitial cystitis and a bladder diverticulum.

Physical examination at the time of admission revealed a temperature of 101.6°, pulse of 104/min., and blood pressure and respiration within normal limits. A large incisional hernia was observed in the place of a previous right pararectal incision, but no tenderness or guarding was noted. Rectal examination revealed tarry stools. A preoperative diagnostic impression of hemobilia caused by communication between the hepatic artery and the common duct was suggested by the initial episode of bleeding from the T-tube. An upper gastrointestinal series was within normal limits and an esophagogram revealed no varices.

The white cell count was within normal limits. The liver function tests were not abnormal during the patient's illness, with the exception of an elevated direct reacting bilirubin (2.85 mg. %) and alkaline phosphatase (20 K. A. units) on one occasion. An intravenous cholangiogram showed visualization of the distal and proximal extrahepatic duct system, but the central portion was hazy. A hepatic artery angiogram was contemplated; the patient, however, developed another episode of acute gastrointestinal hemorrhage. The vital signs stabilized after 1500 ml. of blood was transfused, and an emergency exploratory laparotomy was performed.

Operation

Multiple adhesions containing the small and large bowel were found in the right upper quadrant, and the duodenum was adherent to the area of the common duct. Upon dissection of the posterior wall of the descending duodenum, a 1-cm. pseudo-aneurysmal clot was found interposed between a 3 mm. vessel entering the liver hilus and the right lateral aspect of the common duct. The artery took origin from the gastroduodenal artery. A cavitary area of granulation tissue surrounded this portion of the common duct. Upon further dissection the common hepatic artery was identified to the left of the hepatic duct, and lastly, the right and left branches were demonstrated. It became evident that the cause of bleeding was a communication between an accessory right hepatic artery and the common bile duct with an interposed pseudo-aneurysm of excavated clot. The accessory hepatic artery was ligated and a choledoduodenostomy was performed. The operative procedure, due to multiple adhesions, was complicated by blood loss which could be adequately replaced.

The postoperative course of this patient was uneventful and no further bleeding episodes have occurred. A postoperative cholangiogram revealed a normal duct communication with the duodenum. Upon discharge from the hospital, the patient developed multiple episodes of vomiting, due to partial duodenal obstruction distal to the area of the common-duct anastomosis, explained on the basis of a duodenal ileus. As conservative measures did not improve this situation, a gastroenterostomy was performed. This relieved all symptoms; the patient has remained in good health.

Comment

As a result of an accidental transection of the common duct and possibly some leakage of bile along the T-tube, erosion of an accessory hepatic artery occurred. Two etiological factors must be considered: one possible cause was direct trauma to the accessory hepatic artery at time of cholecystectomy and common-duct surgery; the other factor could have been erosion of the vessel by bile and infection. The recurrence of bleeding was explained by the valve-like mechanism of the above-described pseudoaneurysm or recurrent clot lysis by bacterial enzymes and bile.

Case No. 2

This 34-year-old white female gave a history of jaundice in 1953 associated with right upper quadrant pain. In August 1954, the jaundice recurred, and three weeks later she was operated on in an outside hospital, at which time a cholecystectomy and common-duct exploration were performed. A T-tube placed in the common duct at time of operation was removed in January 1955. Postoperatively, her jaundice had subsided, only to recur with increasing intensity, and associated with hematemesis and melena. In July 1955, the patient started passing tarry or bright red stools in large quantities.

On physical examination this emaciated patient had a firm abdomen due to liver enlargement of four finger breadths below the right costal margin. An upper gastrointestinal series revealed an inactive duodenal ulcer. After multiple transfusions a hemoglobin of 10 gm. associated with recurrent hemorrhage was brought to normal levels. The direct serum bilirubin was 12.2 mg. %, total was 20.7 mg. %, and the alkaline phosphatase was 25.8 K. A. units. The prothrombin time was within normal limits, the BSP showed 13 per cent retention, and the total serum protein was 7.9 gm. % with a reversed A-G ratio of 2.9 and 5.0 gm. %. In view of clear evidence of obstructive jaundice, a preoperative diagnosis of common-duct obstruction due to stone or stricture was made.

Operation

At the time of surgery there were dense adhesions in the right upper quadrant binding the surrounding structures to the porta hepatis. Upon further dissection an old hematoma was noted, and when this was cleared, a sudden gush of blood was seen to originate from the hepatic artery. In an attempt to preserve this essential vessel the artery was repaired, using a pledget of Ivalon. The stricture of the common duct was repaired by choledododuodenostomy. This was accomplished with some difficulty as the proximal end of the common duct was scarred, and only high in the hilus of the liver could a remnant of the common hepatic duct be identified. The postoperative course was stormy, as the patient developed a collection of intraperitoneal bile-stained fluid which had to be drained. In the remaining week of her life she passed large amounts of blood per rectum and also showed evidence of intraperitoneal bleeding, requiring multiple blood transfusions.

The autopsy findings showed massive hemoperitoneum secondary to rupture of the hepatic artery at the site of the repair, biliary cirrhosis secondary to common bile-duct stricture, intrahepatic abscesses, a lysis of the common duct-duodenal anastomosis, and a duodenal ulcer of no clinical importance.

Comment

This patient's history demonstrates the grim aftermath of unfortunate biliary-tract surgery, characterized by common-duct stricture and recurrent episodes of ascending cholangitis. Despite the fact that her condition continued to deteriorate, it was felt advisable to operate, as this appeared to be the only possible avenue of success. The findings of a hematoma suggested past episodes of intraperitoneal hemorrhage.

Only an occasional patient will tolerate ligation of the hepatic artery. Reconstruction of this artery was therefore attempted. Exsanguination from the area of arterial repair clearly indicated that such repairs performed in an infected field are not advisable.

Case No. 3

In September 1958, this patient was admitted to the University of Minnesota Hospitals with a two-year history of epigastric pain relieved by food. A diagnosis of ulceration in the duodenal bulb and a lesser curvature gastric ulcer were established. The patient improved on conservative management; but three months later when massive bleeding occurred from the gastrointestinal tract, an 80-per cent resection of the stomach and a Billroth II reconstruction were performed in another hospital. A cholecystectomy, exploration of the common duct, and insertion of a T-tube were also done. Two weeks after the procedure the T-tube was removed, and the patient was discharged, apparently recovered. One month after this operation the patient was re-admitted with another episode of massive hematemesis and liquid bloody stools, requiring transfusion of 12 pints of blood. The patient was then transferred to the University of Minnesota Hospitals.

At the time of admission the physical examination revealed an old midline abdominal incision; the liver edge was palpated some 4 cm. below the right costal margin. The significant laboratory findings were a BSP retention of 33 per cent, alkaline phosphatase of 12 K. A. units, and serum bilirubin of 2.9 mg. % direct and 5.5 mg. % total. During the first three days of hospitalization the patient had several episodes of upper gastrointestinal hemorrhage requiring replacement with fourteen units of blood. Gastric cooling was instituted with cessation of the bleeding and an operative exploration followed.

Operation

The transverse colon was adherent to the liver. The subhepatic area was found to be filled with a massive blood clot and fresh blood. Upon further identification of portal structures, a large pulsating bleeding vessel was identified as the hepatic artery. A defect with sharp edges was visualized while the bleeding was controlled with compression of the artery through the Foramen of Winslow. An old suture was found in the vicinity of the hepatic arterial tear. This vessel was repaired with running 5-0 arterial silk. The common duct was repaired with interrupted 5-0 chromic catgut sutures, and a Robinson catheter was introduced into the common bile duct for decompression of the biliary tree. With the exception of a minor wound infection, the postoperative course was uneventful.

Comment

This patient suffered both intraperitoneal bleeding as well as hemobilia secondary to an operation on the common duct. The most likely cause was a direct injury to the hepatic artery or traumatization at time of removal of the T-tube.

Discussion

In all three patients bleeding originated from a hepatic artery which communicated with the adjacent common duct, thus producing upper gastrointestinal hemorrhage. In two patients the findings at time of laparotomy showed an abscess-like cavity; in the third patient an opening was observed both in the hepatic artery and in the common duct. The association of hepatic artery common-duct communication with common-duct stricture supports the view that this malady is iatrogenic in origin.

The long history of biliary stricture in the second patient produced cirrhosis and irreversible hepatic changes. In the first and the third cases the relatively short period since the original operation did not allow irreversible hepatic changes to develop and thus treatment by surgical reconstruction could be successfully accomplished. In all three patients the upper gastrointestinal bleeding episodes followed by asymptomatic intervals were similar to the characteristic bleeding found in hemobilia due to hepatic trauma. Jaundice may be caused by absorption of blood from the peritoneal cavity or of bile originating from a common-duct leak and may also be the result of obstruction of the biliary tract. In the second patient bile stasis was undoubtedly due to a biliary stricture; in the other two patients the transient elevation of bilirubin was probably caused by common-duct obstruction produced by blood clots.

Hemobilia must be considered in the differential diagnosis of obscure upper gastrointestinal hemorrhage subsequent to operations on the external biliary system and as an associated finding of common-duct stricture. Presence of a duodenal ulcer identified with a barium contrast examination certainly does not exclude bleeding via the common duct. This type of hemorrhage is difficult to differentiate from other causes of bleeding from the esophagus, stomach, or duodenum. In only one patient was the probable cause suggested prior to surgery. Bleeding around and through a T-tube following common bile-duct surgery should point to this diagnosis. Hemobilia resulting from a communication between the hepatic artery and common duct cannot be excluded by intravenous or T-tube cholangiography. The diagnostic value of identifying a hepatic artery common-duct communication with arteriography requires further evaluation.

Whether reconstruction of an essential vessel such as the hepatic artery can be accomplished must be resolved in each case independently at time of operation. In an infected field such as an abscess cavity, ligation and transfixion of a vessel must be resorted to. The finding in all three patients of an abscess-like cavity containing a mixture of bile with blood in the area of hepatic artery and common-duct communication incriminates bile leakage and direct trauma to the hepatic artery as a causative factor of this entity.

Clearly, the operating surgeon must assume responsibility for this type of hemobilia following operations on the external bile duct system. Prevention must be sought in meticulous dissection and technically proper handling of all the structures while operating on the gallbladder or the common duct.

Summary

Three patient histories of hemobilia secondary to surgical intervention on the biliary tree have been reported. This pathological entity was contrasted with hemobilia due to liver injury. Massive intraperitoneal hemorrhage associated with upper gastrointestinal hemorrhage was present in two patients. Hemobilia should be suspected in all patients with upper gastrointestinal hemorrhage occurring after operations on the biliary tree.

The Penalty of Overweight

Extensive studies have revealed that elevated blood pressure occurs in obese patients in every age group, and in both sexes. With each increase in body weight there is a steady progression of both the systolic and the diastolic blood pressure. — Cyril M. MacBryde, M.D., Signs & Symptoms, Lippincott Co.

Truth in medicine is a goal which cannot be absolutely reached, and the art of healing, as it is described in books, is far beneath the practical experience of a skillful, thoughtful physician. — Rhazes (865-925)

Pseudo-Pseudohypoparathyroidism

KENNETH L. BECKER, M.D.*
DAVID L. HOFFMAN, M.D.**
PAUL E. HERMANS, M.D.**
WILLIAM J. MARTIN, M.D.**
Rochester, Minnesota

IN 1942, ALBRIGHT and associates[1] described three patients, each of whom had rounded facial configuration, short thick-set stature, and short fingers. These three patients also showed clinical signs of tetany, low concentration of calcium, and high concentration of phosphorus in the serum. Resistance to parathyroid hormone as measured by the Ellsworth-Howard test was demonstrated. This clinico-phenotypic syndrome was termed "pseudo-hypoparathyroidism." In 1952, Albright and associates[2] described a thick-set round-faced woman with short fingers and toes who had never manifested any signs of tetany and who had normal serum calcium and phosphorus values. Because of the phenotypic resemblance to pseudohypoparathyroidism and because the parathyroid function appeared adequate, they called this syndrome of anomalies "pseudo - pseudohypoparathyroidism." The purpose of our study was to investigate certain aspects of the calcium and phosphorus metabolism in a patient with pseudo-pseudohypoparathyroidism and to attempt to correlate the findings with the results of prior studies.

Our patient was a 47-year-old man who was short and round faced and who had shortening of the metatarsal and metacarpal bones and normal concentrations of serum calcium and phosphorus. The phenotypic characteristics and preliminary laboratory findings on this patient and his sister have been recorded in a prior study.[3] A survey of a large segment of the family of these two patients is in full agreement with the accepted contention that the condition is hereditary.[4]

Methods

The patient was admitted for study in the Metabolic Unit of the Mayo Clinic in November, 1962. A supervised house diet was administered, except during periods when fasting was required. The patient drank two glasses of milk daily to foster adequate intake of calcium and phosphorus.

On the first day, the per cent of tubular reabsorption of phosphate[5] for a 12-hour overnight period was determined to serve as a control, during which time the patient received 1000 ml. of 5 per cent solution of glucose in water intravenously. The formula utilized for the calculations was:

(Brachymetacarpal Dwarfism)

Endocrinologic
Studies
on
a
Patient

Per cent tubular reabsorption of phosphate =

$$\left(1-\frac{\text{urine phosphate x serum creatinine}}{\text{urine creatinine x serum phosphate}}\right) \text{x } 100$$

On the second night after admission the patient received a continuous infusion of 200 units of parathyroid extract (Lilly) in a solution of 1000 ml. of 5 per cent glucose in water over a period of 12 hours, and the tubular reabsorption of phosphate over this period was calculated. The potency of this parathyroid extract had been previously verified in a normal control individual.

A mock Ellsworth-Howard test was carried out on the fourth day to serve as a control, and an actual Ellsworth-Howard test was performed on the fifth day in the following manner: After a night of fasting, the patient was given 500 ml. of water orally at 7:30 a.m. to ensure adequate urinary flow. At 11:00 a.m. he received an intravenous injection of 200 units of parathyroid extract. Urine was collected hourly from 8:00 a.m. to 2:00 p.m., and the phosphate in each specimen was measured.

During the following week a calcium infusion test was performed as follows: The serum phosphate was determined, and urine was collected hourly from 8:00 a.m. to 12:00 noon for measurement of its phosphate content. Fifteen mg. of calcium per kg. of body weight was administered intravenously as calcium gluconate in 1 liter of isotonic saline during the next eight hours. On the following day, serum phosphate was determined at 8:00 a.m. and 12:00 noon, and urine was collected hourly from 8:00 a.m. to 12:00 noon for measurement of its phosphate content.

Cytogenetic studies were performed and included examination of the buccal smear and chromosomal analysis of the leukocytes cultured from the peripheral blood.

Results

The control values at the beginning of the present study were: 9.6 mg. of calcium, 4.2 mg. of phosphate, 2.3 mg. of magnesium, 15.9 King-Armstrong units of alkaline phosphatase, and 1.2 King-Armstrong units of acid phosphatase per 100 ml. of serum. The concentration of sugar (glucose) was 81 mg., that of creatinine, 0.9 mg., and that of urea, 42 mg. per 100 ml. of blood. The protein-bound iodine was 5.7 micrograms per 100 ml. of serum. The erythrocytic uptake of radioactive triiodothyronine revealed a coefficient of binding of 11.6 (normal: 8.7 to

13.5). At 8:00 a.m. corticosteroids in the blood measured 18.1 micrograms per 100 ml. of plasma, and at 4:00 p.m., 11.6 micrograms. The amount of urinary ketogenic steroids excreted in 24 hours was 9.5 mg., and 11.5 mg. of urinary 17-ketosteroids were recovered in 24 hours. The pituitary gonadotropin assay revealed five rat units, and the estrogen assay, 13 rat units per 24 hours of urine. The basal metabolic rate was −1 per cent.

During the control period, the per cent tubular reabsorption of phosphate was 82.8, while during administration of parathyroid extract it decreased to 70.7. The results of the mock and actual Ellsworth-Howard tests (Table 1) illustrate the slight phosphaturic response induced by the parathyroid extract. The calcium infusion test (Table 2) lowered the urinary phosphate and elevated the serum phosphate values.

The buccal smear was chromatin-negative. Karyotypic analysis of the cultured leukocytes revealed the uniform presence of 46 chromosomes, including a morphologically normal X and Y chromosome.

Comment

Endocrine studies of pseudo-pseudohypoparathyroidism reported in the literature are difficult to evaluate because of the diversity of the cases which have been included under this nosologic term. Pseudo-pseudohypoparathyroidism has been described in association with gout,[6] diabetes mellitus,[7,8] Turner's syndrome,[9-11] hypothyroidism,[8,9] diminished adrenal function,[8] and absence of pituitary gonadotropin in the urine.[8]

Parathyroid Hormone Responsiveness

The correct evaluation of parathyroid function and parathyroid hormone responsiveness is vital in the differential diagnosis between pseudohypoparathyroidism and pseudo-pseudohypoparathyroidism. The first and most important criterion is that the patient with pseudo-pseudohypoparathyroidism, by definition, can never manifest the clinical symptoms or signs of hypocalcemic tetany, while tetany is common in pseudohypoparathyroidism. The final diagnosis depends on laboratory data. By original definition, serum calcium and phosphorus values must be normal in pseudo-pseudohypoparathyroidism, whereas in pseudohypoparathyroidism, the value of calcium is commonly low and that of phosphate is elevated.

Many authors have emphasized a normal response to parathyroid hormone as a requisite feature of the clinical entity of pseudo-pseudohypoparathyroidism, and yet the original patient described by Albright and associates[2] did not respond to the Ellsworth-Howard test. Among 12 patients undergoing an Ellsworth-Howard test whose cases have been reported, four have responded with apparently significant phosphaturia[6,12-14] and eight have not.[2,7-9,15-18] In our patient, only slight phosphaturia resulted from the parathyroid extract. The erratic response of normal individuals to the Ellsworth-Howard test has been noted frequently. Dent[19] men-

tioned a variable phosphaturic response to parathyroid extract in four normal persons, and, for similar reasons, the value of the Ellsworth-Howard test in separating the abnormal from the normal individual has been repeatedly questioned.[20-23] The various explanations for the inconsistent response of normal individuals to parathyroid extracts have included varying potency of the commercial parathyroid preparations,[15] inadequate presence in the extracts of only one of two hypothetic parathyroid moieties, and the interfering effects of normal diurnal variations in phosphate excretion.[19]

Tubular Reabsorption of Phosphate

Perhaps it has not been sufficiently emphasized that phosphaturia is a poor index of response to the parathyroid hormone.[24] One of the factors controlling phosphaturia is the glomerular filtration rate. An increase in phosphaturia may be due merely to an increased glomerular filtration rate,[23] and a bona-fide phosphaturic response may be masked by a lowered glomerular filtration rate. A more significant index of the renal effect of parathyroid hormone is determination of a change in the tubular reabsorption of phosphate. Phosphate is completely filtrable through the glomerular membrane, and the phosphate which is found in the urine is that which has not been reabsorbed by the renal tubules. One of the primary physiologic effects of the parathyroid hormone is control of the amount of phosphate that is reabsorbed by the tubules.[25] Tubular reabsorption of phosphate is the amount of phosphate filtrated by the glomerulus minus the amount of phosphate found in the urine. The filtered load of phosphate may be calculated by the product of the glomerular filtration rate and the serum phosphate.

Thus the tubular reabsorption of phosphate includes three factors which affect or reflect phosphate excretion: urinary phosphate, serum phosphate, and the glomerular filtration rate. The overnight tubular reabsorption of phosphate test before and after the administration of parathyroid extract that was used in our patient was devised by Becker, Purnell, and Jones[26] as a clinical index of endogenous parathyroid activity. Our patient responded in a normal fashion with a significant reduction in tubular reabsorption of phosphate in the period that followed the injection. If the Ellsworth-Howard test alone had been utilized, one would have had to conclude that there was very little response.

Calcium Infusion Test

The calcium infusion test was devised by Howard and co-workers[27] as a method of evaluating parathyroid function. It was reasoned that exogenous hypercalcemia decreases endogenous parathyroid secretion and will consequently diminish urinary phosphate excretion and increase the serum phosphate. The test yields different results depending on the number of hours after the infusion that the blood samples are taken. For example, in our patient, the phosphate value on the morning prior to the calcium infusion was 4.0 mg. per 100 ml. of serum, and on the following morning it had increased to 5.7 mg. By the afternoon of the same day, however, the phosphate value had decreased to 2.9 mg. (Table 2). The variation in the times that blood and urine were collected may explain the inconsistent response of patients with pseudo-pseudohypoparathyroidism to the calcium infusion test.[6-9,13-18]

As an alternate method of demonstrating the normal response of a patient to parathyroid extracts, daily intramuscular injections of the extract for several days, followed by determinations of the serum calcium and phosphorus, have been suggested. A normal response would be characterized by an increase in the serum calcium value and a decrease in the serum phosphate value.[21-23,28]

The relationship between pseudohypoparathyroidism and pseudo-pseudohypoparathyroidism remains obscure, especially since both have allegedly occurred in the same family.[29] It has been claimed that pseudohypoparathyroidism may represent the full expression while pseudo-pseudohypoparathyroidism represents the forme fruste of the same syndrome;[30] but the evidence for such postulation is not incontrovertible.[31,32] Pseudo-pseudohypoparathyroidism is not an endocrine disease, but a "syndrome of multiple congenital defects."[32] However, the appellation is useful because it calls attention to the endocrine disease from which it must be differentiated, that is, pseudohypoparathyroidism.

Summary

Endocrine determinations have been performed on a man with the physical stigmata of pseudo-pseudohypoparathyroidism. Calcium metabolism and phosphate metabolism were studied after parathyroid extract and calcium infusions. A procedure for evaluating the parathyroid hormone responsiveness has been suggested to distinguish pseudohypoparathyroidism from pseudo-pseudohypoparathyroidism, the differential diagnosis frequently being dependent on laboratory data.

Demonstration of the resistance to parathyroid extract in pseudohypoparathyroidism as opposed to the normal responsiveness in pseudo-pseudohypoparathyroidism can be accomplished by the determination of the per cent of tubular reabsorption of phosphate before and after the injection of parathyroid extract. A significant reduction in tubular reabsorption of phosphate in the period that follows the injection will prove normal renal responsiveness and thus further substantiate the diagnosis of pseudo-pseudohypoparathyroidism.

Acute Lymphangitis and Cellulitis

● Diagnosis ● and ● Therapy

ALEXANDER SCHIRGER, M.D.*
WILLIAM J. MARTIN, M.D.*
JOHN A. SPITTELL, JR., M.D.*
Rochester, Minnesota

ACUTE LYMPHANGITIS and cellulitis occasionally complicate both idiopathic and secondary lymphedema and at times occur in patients without permanent lymphedema. The clinical picture may be incorrectly interpreted, and "chronic" phlebitis, recurrent phlebitis, or chronic deep venous insufficiency may be incorrectly diagnosed. The purpose of this presentation is to review briefly the clinical picture of acute lymphangitis and cellulitis and to outline a plan of management.

Clinical Picture

Acute lymphangitis and cellulitis usually are of abrupt onset. Typically, the patient is seized out of good health by prostration, high fever, shaking chills, and profuse sweating. The fever may reach 104 to 105° F. (oral) and attain its peak within one or two hours. Several hours may elapse after the fever appears before the extremity becomes painful to touch. On examination, the patient appears acutely ill and flushed and often is perspiring profusely. Shaking chills are almost an integral part of the picture. The affected extremity appears red and hot and often is tender to touch. The redness may be in streaks indicating the course of the subcutaneous and deep lymphatics, or it may be in diffuse areas not unlike those seen in erysipelas, indicating diffuse cellulitis of the structures through which the inflamed lymphatics course. There may be inguinal or axillary tenderness due to inflamed lymph nodes in these regions. If untreated, usually the acute lymphangitis subsides gradually within a few days, and a feeling of malaise remains. The extremity is painful and swollen for some time after subsidence of acute symptoms. The swelling usually increases with each recurrent episode.

Etiology

Acute lymphangitis and cellulitis may complicate pre-existing lymphedema, or the recurrent infectious episodes may constitute the mechanism by which lymphedema develops. In a review of 131 patients[1] with idiopathic lymphedema seen at the Mayo Clinic, single or recurrent episodes of lymphangitis or cellulitis occurred in 32 patients. Trichophytosis occurred in 11. In a separate study of 80 patients with secondary lymphedema of the leg, Smith and associates[2] found that lymphedema was infectious in origin in 43 patients. In 21 of these, the history of single or repeated episodes of acute cellulitis and lymphangitis was elicited, and in 14 instances there was active trichophytosis. In all 43 patients, acute infection on one or more occasions preceded the persistent lymphedema. While lymphedema of the idiopathic type was complicated by acute lymphangitis and cellulitis in approximately 20 per cent of the patients, only two with lymphedema of the leg secondary to malignancy gave a history of recurrent lymphangitis. This discrepancy undoubtedly reflects the longer duration of the lymphedema in the patients without evidence of underlying malignant disease. Etiologically, streptococci[3-5] are said to be the most common offenders; however, staphylococcus[6] has been incriminated, and dermatophytosis probably has a significant contributing part.[7]

---

*Section of Medicine, Mayo Clinic and Mayo Foundation.

Differential Diagnosis

Since acute lymphangitis with cellulitis complicating lymphedema is confused most frequently with acute thrombophlebitis, it may prove helpful to reiterate several diagnostic points in the differentiation of these two conditions. The acute onset of fever, chills, and prostration in acute lymphangitis and cellulitis is in contrast to the more gradual onset of symptoms in thrombophlebitis. In thrombophlebitis, fever seldom reaches the degree seen in acute lymphangitis and cellulitis, and chills are absent except in septic thrombophlebitis. On examination, the acutely inflamed red, tender, moderately swollen leg in acute lymphangitis and cellulitis is easily recognized by an experienced observer as differing from the edematous leg in acute venous thrombosis. Acute thrombophlebitis usually causes a discomfort that is deeper in the tissues of the calf and thigh and is more nagging. On examination in acute thrombophlebitis, the tenderness to touch that is characteristic of acute lymphangitis is absent, and there is tenderness to deep palpation of the calf and thigh along the course of the main venous channels. Redness is likewise absent in thrombophlebitis, but the venous pattern is increased because of venous obstruction. This latter finding is characteristically absent in a patient with acute lymphangitis and cellulitis. Finally, in patients who are in the chronic stage of either disease, deep venous insufficiency with its characteristic pigmentation about the inner areas of the ankle and the lower part of the leg, evidence of previous stasis ulceration, current stasis ulcers, atrophy of the skin, venectasiae, and localized varices are easily distinguishable from the hallmarks of chronic lymphedema manifested by a firm nonpitting, diffuse swelling of the leg and foot with the characteristically square toes and a thickened piglike skin. This appearance, of course, during the acute episode, is modified by the superimposed acute lymphangitis and cellulitis. The physician should be constantly aware of the differential diagnosis so that a patient with acute lymphangitis and cellulitis may not only be given proper treatment, but also not be exposed to prolonged, costly, and potentially hazardous anticoagulant therapy as well as the mental trauma which occasionally is inflicted on patients whose conditions have been mistakenly diagnosed as "chronic" thrombophlebitis. Correct recognition of the two conditions will prevent the even graver mistaking of an acute deep thrombophlebitis for acute lymphangitis, with the potential serious and disastrous effects that could follow omission of indicated anticoagulant therapy.

Therapy

On the basis of our preliminary[8] and subsequent experience, we have evolved the following plan for treatment of patients with acute lymphangitis and cellulitis. Whenever possible the patient is hospitalized and placed at bed rest so as to minimize movements of the affected extremity. Bathroom privileges are allowed in preference to the use of bedpans. The severe pain during the acute episode may require administration of sedatives or mild analgesics, and salicylates will often afford symptomatic relief.

Antibiotic Therapy

The most important factor in the treatment of a patient with acute lymphangitis and cellulitis is the immediate administration of proper antibiotic therapy. In patients who are not sensitive to penicillin, we give 600,000 units of procaine penicillin G twice daily, and this dosage is continued for 24 to 48 hours after the patient has been completely afebrile. In patients sensitive to penicillin, erythromycin is given in a 250-mg. dose every four hours initially; after the temperature has subsided this dose is given every six hours. This alternate regimen is likewise continued until the patient has remained afebrile for 48 hours. In addition, warm, moist compresses to the extremity often give symptomatic relief from the discomfort of the inflamed skin involved by the acute cellulitis. Once fever has subsided, the patient, using a proper elastic support, is allowed out of bed; this elastic support can be in the form of Ace bandages, a 100-per cent para rubber bandage, or more recently a made-to-measure foot-to-knee Jobst stocking. Five milligrams of a thiazide diuretic such as bendroflumethiazide (Naturetin) given every other day may also aid in control of edema. When this is done, urea in the blood and potassium in the serum should be checked periodically.

Long Term Prophylactic Therapy

In our opinion, any patient who has had one or more episodes of acute lymphangitis and cellulitis and who has lymphedema of the extremity is a potential candidate for intermittent long-term antibiotic prophylaxis. We have customarily prescribed benzathine penicillin G in amounts of 1,200,000 units administered intramuscularly once a month or phenoxymethyl penicillin in amounts of 250 mg. four times daily for five to seven days of each month. In individuals allergic to penicillin, erythromycin, in a dose schedule indentical to that employed for phenoxymethyl penicillin, is prescribed. Our results to date have been gratifying, and to most patients the resulting freedom from recurrent and incapaciting episodes of acute lymphangitis and cellulitis, as well as the prevention of progressive lymphedema, has constituted ample reward for the small inconvenience in time and expense posed by the long-term antibiotic program.

Treat Associated Dermatophytic Infection

In addition to the program of antibiotic therapy and to the use of proper elastic support, the patient with recurrent lymphangitis and cellulitis should be carefully examined and treated for any associated dermatophytic infection. We instruct patients in the proper hygiene of feet and in the application of an appropriate antifungal agent such as triacetin ointment and powder. In selected patients, we have resorted to the administration of griseofulvin in the hope of eradicating the fungal infection and thus eliminating a portal of entry for the organism responsible for the repeated episodes of lymphangitis and cellulitis. Finally, in those patients with postmastectomy lymphedema, proper physiotherapeutic measures as described by Stillwell[9] for the care of the arm should be employed.

Summary

Acute lymphangitis and cellulitis is not an uncommon disorder. Physicians should be aware of the differential diagnosis between acute lymphangitis and cellulitis and acute deep venous thrombosis. Acute lymphangitis and cellulitis either may complicate lymphedema of the idiopathic or secondary type or may occur de novo, eventually giving rise to infectious lymphedema.

The treatment of choice is the administration of proper antibiotic therapy during the acute phase in conjunction with bed rest and symptomatic measures.

The long-term management of the condition consists of intermittent antibiotic prophylaxis and the use of proper elastic support, supplemented at times by the intermittent use of a thiazide diuretic and treatment of dermatophytic infection, if such is present.

A Tribute to Hippocrates

We physicians revere Hippocrates because he was the first man to teach, first, that many diseases clear up best if the physician does not meddle too much, and, second, that medicine can advance only when it breaks away from magic. Gradually, through the two milleniums before the birth of Christ, physicians had been coming to see that some diseases are due to injury and contagion and the wearing out of parts, but so far as we have a record, Hippocrates was the first to go the whole way and state that no disease is purely miraculous in origin.

And if through the ages, religiously minded people had only listened to Hippocrates and had given his successors the freedom to dissect, to perform autopsies, to experiment on animals, and to report honestly and fearlessly what they found, how almost certain it is that today medical knowledge would be hundreds of years ahead of where it is, with tuberculosis and cancer and arthritis perhaps only memories of the past. PRO-BANTHĪNE®

(propantheline bromide)

Historically, reduction of acid and motility in peptic ulcer has been approached through the use of antacids, dietary management and surgery.

Since 1953, however, Pro-Banthīne used alone or in addition to other measures has contributed importantly to achieving both of these goals. It has been shown repeatedly that adequate doses of Pro-Banthīne will significantly inhibit gastric acid secretion and reduce gastrointestinal motility.

So dependable have these actions been that now, for many, standard treatment of peptic ulcer and several allied conditions has become antacids *plus* Pro-Banthīne, dietary management *plus* Pro-Banthīne, surgery *plus* Pro-Banthīne, or some combination of the three.

Pro-Banthīne has become the most widely prescribed anticholinergic for patients with peptic ulcer, functional hypermotility, irritable colon, pylorospasm and biliary dyskinesia because patients respond favorably to its therapeutic actions.

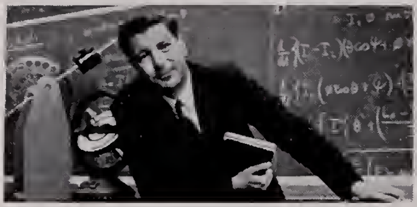
Side Effects and Precautions—Urinary hesitancy, xerostomia, mydriasis and, theoretically, a curare-like action may occur. The drug is contraindicated in patients with glaucoma or severe cardiac disease.

Dosage—The maximal tolerated dosage is usually the most effective. For most *adult* patients this will be four to six tablets daily in divided doses. In severe conditions as many as four tablets may be given four times daily. Pro-Banthīne (brand of propantheline bromide) is supplied as tablets of 15 mg. and, for parenteral use, as serum-type ampuls of 30 mg.

SEARLE
Chicago, Illinois 60680
Research in the Service of Medicine

Stelazine® brand of trifluoperazine
will calm your anxious working patient—with little or no drowsiness

When anxiety interferes with work, your patient needs a drug that will calm without causing undue drowsiness. With Stelazine (trifluoperazine, SK&F), you can promptly control the anxiety without producing the sedation seen with certain other agents. Anxious patients can remain active during therapy.



Stoll[1] used the drug in 50 patients with anxiety, and noted: "There was no drowsiness in this group of patients and, because of their alertness and less impaired concentration, they were able to continue with and, in some cases, return to their daily work."

Stelazine (trifluoperazine, SK&F) produces a fast therapeutic response—often within 24 to 48 hours. The convenient b.i.d. regimen frees patients from the need for a midday dose.

Principal side effects, usually dose-related, may include mild skin reaction, dry mouth, insomnia, fatigue, drowsiness, dizziness, amenorrhea and neuromuscular (extrapyramidal) reactions. Muscular weakness, anorexia, rash, lactation and blurred vision may also be observed. Blood dyscrasias and jaundice have been rare. Use with caution in patients with impaired cardiovascular systems. *Contraindicated* in comatose or greatly depressed states due to CNS depressants and in cases of existing blood dyscrasias, bone marrow depression and pre-existing liver damage.

Before prescribing, see SK&F Product Prescribing Information.

Photograph professionally posed.

A Triumph of Organ-Grafting Technique and Its Moral Problems*

SENSATIONAL INDEED are the journalistic accounts of the most recent challenge to surgical skill in devising successful organ transplantation, but seldom do these publicity releases complete the public case records. The full story, with all its obsessive drive, anxiety, frustration, heartache, and often tragedy, can only be surmised.

Some idea of the problems in the otherwise optimistic picture may be obtained from comments such as those of Joshua Lederberg, the distinguished Nobelate geneticist, who has philosophically scanned the situation, or of J. Russell Elkington, who has painstakingly reviewed two hundred and forty-four reported kidney-transplant operations. Both Lederberg and Elkington raise questions about the moral problems, which the triumphs of surgical technique cannot dodge.

In a remarkably clear manner Victor Cohn has discussed some of the ethical problems which may be involved. The relation of these problems to "medical ethics" is not so much concerned with medical etiquette between members of the medical profession as it is with the more basic morality which lies at the base of the patient-doctor relationship.

Historically the current situation is somewhat analogous to what happened in the 17th century, when blood transfusion was first undertaken as a practical clinical procedure in an effort to apply William Harvey's 1628 demonstration of the blood circulation. The attempts failed tragically, because of technical ignorance. The moral problem then was clear: one could not undertake blood transfusion without the risk of death, and the effort was condemned by social fiat. Two centuries were required to surmount the technical problem. It was only after Karl Landsteiner (1868-1943) revealed the factors operating in the incompatibility of blood groups, that transfusion gradually became a successful and socially approved procedure.

In the current situation in organ transplantation it seems likely that technical understanding and skill will triumph much more rapidly than was the case with blood transfusion. On the other hand, it appears that the moral problems involved may multiply.

Stanford University's Nobel Award geneticist, Joshua Lederberg,** asks such searching questions as:

> "When surgeons are able to transplant hearts, who will choose which dying patients get the new ones? Who will decide whether the organs of a dead person should be transplanted directly or maintained in frozen storage, and who will decide the price?"

Lederberg points out that the transplantation of hearts, livers, and even complete limbs may be relatively easy within the next twenty years. The moral problems raised by the potential success of these efforts are as serious in other parts of the world as with us.

Lederberg concludes that the future of organ transplantation, which may even include gonads with resulting benefits, may result in serious controversy. All parents may be expected to insist that their children be given the intelligence of genius. Who will decide how to use this genetic pool? These problems are too important to be entrusted merely to biomedical scientists or to members of the health professions. There must be careful and detailed public study of these matters, with solutions dependent upon moral, social, and economic factors, and most importantly, upon enlightened public opinion.

Elkington, in reviewing several hundred kidney transplantations, finds increasing survival periods for recipients as technical skill improves. Chances of surviving a year are now about 75% for patients who get a kidney from a close relative. However, the moral problem remains: *is this life extension of the recipient worth the potential reduction in the life span of the donor?* Many factors must be considered in the decision: relative ages, potential productiveness, relative contributions and value to the community, and individual consciences. As Victor Cohn indicates, it is to the lasting credit of the health team personnel that these considerations are carefully weighed and all aspects of the case fully explored before the team decides to let nature take its course or, on the contrary, to intervene.

Technique and Reason

Technical surgical skill already seems available. The major current block is immunological, relating to the process of rejection. With the use of mercaptopurine compounds to block antibody formation, and with radiation of the spleen to further reduce the appearance of rejection factors, it seems that experimental study will soon result in successful applications to clinical practice in organ transplants. However, much judgment will be required in control of the immunological inhibition. Blocking the immunological factors must not be achieved at the risk of interfering with the long-range welfare of the recipient of the transplant.

It now seems well established that kidneys may be successfully transplanted from one identical twin to another. But how many of us have altruistic identical twins handy, if one of our kidneys goes wrong? Or suppose I were the healthy twin: would I be ready to part with one of my kidneys for the benefit of my twin, never to regret my action?

A two-way responsibilty exists: if I am the healthy person and wish to be generous, would I be wise to sacrifice one of my healthy organs if I had heavy family responsibilities? If I am the sick one, would I be justified in calling on even a close relative to yield a healthy organ for me, merely to keep me alive for another year or so?

The ethical issue for the donor is slight: self-sacrifice is commended for generosity and for social welfare. Yet self-sacrifice is not always justifiable even on the basis of social expediency, let alone enlightened self-interest. From the standpoint of the recipient it does not seem that anyone has the right to expect that someone else would willingly give up some part of his body for the recipient's benefit or even his life. The problem is complicated by our sentimentalized fear of death. Few of us have disciplined ourselves to face death with dignity and resignation when our time comes.

A Scientific Approach to the Ethical Problem

The ethical problem is not then satisfactorily answered by reference either to hedonism* or to Platonic idealism:* the two ancient and conflicting theories of justifying human conduct, which are still being debated. Nor will help come by referring to the 19th century compromise of pragmatic utilitarianism, the idea of the greatest good for the greatest number. Some light may be found, however, in exploring the consequences of evolutionary principles from the

Lederle

basis of Warner Fite's naturalistic individualism. Actually, ethical theories have lost contact with the realities of today, and philosophers have failed in communication with us, just when we need them most.

There is, however, a pragmatic scientific approach to the problem of our motivation and conduct. *This requires full self-consciousness and both intellectual and emotional honesty: traits, unfortunately, not well cultivated among us.* I am referring to a moral approach to living on the basis of an understanding of the complex factors involved in maintaining desirable interpersonal relationships.

The relationships between individuals or between groups of individuals are delicately poised on many intangibles; however, some generalities are emerging. As agreed upon a couple of decades ago by a number of distinguished biologists and philosophers, it is possible to express a naturally operating principle governing human relationships in scientific terms, that is, in a manner compatible with biological laws of adaptation and survival. This principle may be considered to be naturally operative in the sense that it continues to be effective whether we are conscious of it or not, or whether we like it or not.

Ethicogenetic

This ethical principle, as stated a quarter of a century ago, in a discussion which I called "Ethicogenesis," is: The probability of the survival of a relationship between individuals or groups of individuals increases with the extent to which the relationship continues to be mutually satisfying.

What does this ethicogenetic principle mean in organ transplanting?

First, there is *the patient,* anxious, trying to repress the unpleasant contemplation of death, and yet appalled at the sudden responsibility of accepting something truly valuable beyond price from someone else. Yet for every ordinary patient, even if he is well self-disciplined, there is the will to live at any cost. This is essentially the quintessence of hedonism.

Second, there is *the surgeon,* on the surface cool, calm, collected, self-reliant in technical skill, troubled only by the possibility of failure through lack of knowledge and experience of how to control the immune processes in probable rejection, and also concerned over the delicacies of obtaining a suitable and willing donor. He represents the pragmatic utilitarian.

Third, there is *the donor,* often over-eager to sacrifice because of some subconscious guilt complex, or simply happy to give something truly important for a loved one. Here is the personification of Platonic idealism, on which our acceptable Judeo-Christian ethic is based.

One might think that this categorization covers the interpersonal relationships involved in organ transplantation. However, the situation is vastly more complex, as a moment's reflection will reveal.

Consider, for example, the somewhat related matter of blood transfusion, now under socially acceptable methodology, but with continuing difficulty in obtaining donors in spite of every inducement. Or consider the more emotionally charged problems of artificial insemination, which are still under vigorous social debate. In these instances the technical aspects of the situations have been adequately and successfully solved; and risks to the living are minimal. This is not the case, however, with organ transplantation.

There remains the high probability, in spite of sensational publicity, that an organ transplant will be rejected. In this case the recipient is clearly as badly off as ever, and the donor is worse off. The recipient may have gained a few more weeks of life, but how about the potential reduction in the fullness of living for the donor? And what profit to the surgeon, except the dubious publicity for the attempt, with soft-pedalling of the failure? This all lacks the clean smell desirable in the health professions.

The establishment of socially acceptable organ banks might reduce some of the moral difficulties inherent in organ transplantation, but the technical problems are as yet unsolved. Even donation of organs after death to an organ bank might have complications. There might also be difficulties for recipients

Your patient doesn't have to be in the Masters to get sprains and strains

Regardless of the etiology of muscle sprain or strain, 'SOMA' COMPOUND helps relieve pain and relax muscle. Patient comfort can be increased and recovery time shortened.

Soma® Compound

carisoprodol 200 mg., acetophenetidin 160 mg., caffeine 32 mg.

rational combination therapy for sprains and strains: relaxes muscle, relieves pain. Also available with ¼ gr. codeine as 'SOMA' COMPOUND with CODEINE: carisoprodol 200 mg., acetophenetidin 160 mg., caffeine 32 mg., codeine phosphate 16 mg. (Warning: may be habit-forming.)

BRIEF SUMMARY

'SOMA' COMPOUND; 'SOMA' COMPOUND plus CODEINE: carisoprodol, acetophenetidin, caffeine, codeine phosphate. *Warning: Codeine may be habit-forming.* **Indications:** 'Soma' Compound and 'Soma' Compound with Codeine are indicated for relief of pain and stiffness in traumatic, rheumatic and other similar conditions. **Contraindications:** Allergic or idiosyncratic reactions to carisoprodol or codeine. **Precautions:** *Acetophenetidin*—May damage the kidneys when used in large amounts or for long periods. *Codeine*—Should be used with caution in addiction-prone individuals. *Carisoprodol*—Like other central nervous system depressants, should be used with caution in patients with known propensity for taking excessive quantities of drugs and in patients with known sensitivity to compounds of similar chemical structure, e.g., meprobamate. **Side effects:** *Codeine*—Nausea, vomiting, constipation, and miosis. *Carisoprodol*—The only side effect reported with any frequency is drowsiness, usually on higher than recommended doses. One instance each of pancytopenia and leukopenia occurring when carisoprodol was administered with other drugs has been reported as has an instance of fixed drug eruption with carisoprodol and subsequent cross-reaction to meprobamate. Rare allergic reactions, usually mild, have included one case each of anaphylactoid reaction with mild shock and angioneurotic edema with respiratory difficulty, both reversed with appropriate therapy. Other rarely observed reactions have included dizziness, ataxia, agitation, increase in eosinophil count, and gastrointestinal symptoms. Massive overdosage may produce coma and/or mild shock and respiratory depression. **Dosage:** 'Soma' Compound and 'Soma' Compound with Codeine, one or two tablets three times daily and at bedtime. **Supplied:** 'Soma' Compound, orange tablets, each containing carisoprodol 200 mg., acetophenetidin 160 mg., and caffeine 32 mg. 'Soma' Compound with Codeine, white, lozenge-shaped tablets, each containing carisoprodol 200 mg., acetophenetidin 160 mg., caffeine 32 mg., and codeine phosphate 16 mg. Narcotic order form required. *Before prescribing, consult package circular.*

WALLACE LABORATORIES
Cranbury, N. J.

C90-3518

as a result of emotional factors in the anonymity of the donor. Perhaps these matters may be more satisfactorily solved by utilizing mechanical devices for functional purposes, as is possible in kidney failure and in amputations. Indeed, some brave biomedical scientists are busily experimenting with artificial hearts, and some cardiovascular devices have already been successfully developed for application clinically. Here technique may truly triumph with relatively little fear of ethical complications.

Psychosocial Factors

Further to be considered is the overwhelming complex of the psychosocial factors involved, not only with respect to the three principles in the organ-transplant drama, but also in regard to the social environment in which each respectively moves, and in the larger environment of the whole community. It is doubtful that harmonious interpersonal relations between recipient, donor and surgeon, and between these and their respective communities, can be maintained under the harsh realities of probable failure and inevitable death. In anticipation, these interpersonal relations seem so pleasant and promising, but the mutual satisfactions necessary for the survival of harmony are often too delicately balanced to last.

If those who are enmeshed in the particular interpersonal relationship under consideration wish it to continue, then it is clearly incumbent upon each to do what is possible to make the relationship satisfying to the others involved in it. This requires calm, honest, and open discussion among the recipient, the donor, and their respective families, under the leadership of the surgeon, and with the guidance of religious advisors.

Ethical Responsibility of the Surgeon

Here, then, are the ethical responsibilities of surgeons in organ transplantation: (1) to undertake nothing until the technical procedures are fully under control, including the as yet unsolved immunological problem of transplant rejection; (2) to discuss the whole matter carefully and in detail with prospective recipient, proposed donor, family and religious advisors; (3) to be well versed in ethical theory and in psychology, so that individual motivations can be detected, exposed, and discussed, and (4) to be prepared to do everything possible to maintain harmonious interpersonal relations among recipient, donor, family and religious advisor, no matter what the outcome of the endeavor may be.

The *moral problems of organ transplantation* are not the exclusive responsibility of surgeons or of biomedical scientists who may be working on the technical details which must be solved for clinical success. Nor are they the primary responsibility of prospective recipients or donors. They *are the responsibility of all intelligent people.*

It would be wise for biomedical scientists and members of the health professions to have no false pride or intellectual arrogance about the matter. It would be expected that these intellectual leaders would examine their own individual motivations and get acquainted with the rudiments of ethical theories and their historical development. Also they would be wise to remember that among the consequences of biological evolution and its basic principle of harmonious adaptation for survival, is the proposition that the probability of survival of relationships between humans, as individuals or as groups, increases with the extent to which these relationships are mutually satisfying.

Sleeping better, Mrs. Smith?

My, yes! I'm not tired out anymore.

Headaches still bother you?

Not at all. I feel wonderful!

Mmm. Normal. Must be taking
your Regroton.

One a day at breakfast.
Sure is easy on me.

Fine. I'm cutting you down to
half a tablet daily.

Thanks for everything, Doctor.
See you on the 3rd.

...excellent response to Regroton,
from 196/120 to 145/90.

Composition: Each tablet contains chlorthalidone, 50 mg., and reserpine, 0.25 mg.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: Discontinue 2 weeks before general anesthesia, 1 week before electroshock therapy, and if depression or peptic ulcer occurs.
Precautions: Reduce dosage of concomitant antihypertensive agents by one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take particular care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side Effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.

Availability: Bottles of 100 and 1000 tablets.
Average Dosage: One tablet daily with breakfast.

Technical Factors in the X-Ray Examination of the Chest

THE ROENTGEN examination of the chest can be one of the most valuable specific procedures in medical diagnosis. When one considers that it is possible, under favorable circumstances, to detect a lesion in the lung as small as 2 or 3 mm. in diameter, to determine the presence of an acute pathological process within a few hours after its onset, and to find the evidences of chronic disease before the onset of symptoms or physical signs, the value of a good roentgen procedure is apparent.

One of the handicaps in the X-ray examination of the chest results from the use of one film and one exposure for the entire thorax from apex to base, although there are striking differences in thickness and density of the different portions of this area. Ideally, we should make at least four different exposures, in order to equalize these differences. A second impediment is occasioned by large areas of the lung which are covered by denser parts such as the ribs and mediastinal structures. However, such difficulties can be compensated for in a variety of ways. The importance of the lateral view has been demonstrated not only in determining the location and distribution of a lesion which is known, but also in finding an abnormality which may not be visible in the posteroanterior view.

In addition, the X-ray examination of the chest may require various oblique projections, the apical lordosis, and the posteroanterior lordosis views. Structures which are not clearly visualized in one position may become apparent in another. Pulmonary infarcts not clearly visible in the conventional positions may be demonstrated when certain oblique projections are used. The same would apply to many other pathological processes.

In the effort to overcome the handicap of the varying degrees of radiographic density in the thorax resulting from the chest wall, the mediastinal structures, and other dense areas, techniques utilizing highly penetrating radiation are now in use. Such films tend to give a gray appearance and do not exhibit the striking contrast of black and white which characterizes chest roentgenograms made with low voltage radiation. This has led many physicians who are not fully aware of the physical factors and the diagnostic difficulties of chest examination to be critical of such films. But the fact is that these films are of much greater diagnostic value than the high contrast film. Experimental studies are under way using radiation factors which are equivalent to 6,000,000 volts; such films demonstrate structures in the mediastinum hitherto scarcely observed. Such techniques are limited in usefulness, however, because apparatus of such power is not generally available.

The radiographic examination of the chest in the symptomatic patient, as conventionally practiced, represents a screening procedure. Beyond this a number of other methods should be undertaken to determine more definitively the anatomical location of the abnormality and its exact nature. These methods include over-exposed films using a grid diaphragm, a variety of positions, and varying degrees of exposures. In addition the use of body section roentgenography, (tomography or planigraphy) may be most helpful, but this procedure is not used widely enough. By this means the structures surrounding any particular area may be blurred out sufficiently so that the shadow of the disease process or of an air-filled bronchus will stand out vividly. In most cases abnormalities of the major bronchi, especially tumors, can thus be clearly revealed. Furthermore, cavities in the lung, small nodules, as well as many other conditions can be more clearly delineated; in some instances lesions not seen in the ordinary roentgenogram become visible. For the demonstration of the segmental bronchi, bronchography with contrast medium should be used. Finally, the pulmonary blood vessels may now be readily demonstrated by injection of contrast medium either intravenously or by catheterization directly into the pulmonary artery. In recent years efforts have been made to delineate the bronchial arteries with contrast. Such a procedure could be of great value in differential diagnosis, especially of tumors and other such chronic processes. The demonstration of the azygos vein can be accomplished readily by injection into a rib of con-

trast medium, and in rare situations this may improve our diagnostic acumen.

All of the above procedures are applicable to the patient with symptoms in whom a specific lesion is likely to be present. The roentgen examination of the asymptomatic individual, whether during a mass survey or individually as a part of a routine examination, presents a different problem. It is obviously impractical to undertake such elaborate procedures when the probability of discovery of a lesion is relatively small. Commonly only one posteroanterior view is made under these conditions. If it were possible, as it should be, to use two films for a routine examination, I believe stereoscopic posteroanterior views would be the best procedure. The chief errors in such routine examinations are the failure to detect the early lesions of tuberculosis, very small tumors, or other minimal pathology. Such errors are due to superimposition by overlying structures, especially the ribs; the shift in position in two films made with the X-ray beam at different angles tends to overcome this handicap. If three films were available, obviously, stereoscopic posteroanterior and lateral views would be the best.

Finally, I would urge that the technique of chest X-ray examination be given close attention and consideration by all those who are using it. It is much too valuable a procedure to be attempted casually. Our sins of omission, our failure to recognize small or early lesions in the lung, are clearly apparent to anyone who has studied the previous roentgenologic history of many patients. A large part of these failures is due to poor technique. The roentgen detection and identification of pulmonary disease processes, especially when the lesion is early or small, are difficult enough. It is inexcusable that we should add to these difficulties by inadequate use of the technical facilities available to us.

Methuselah,* Here We Come!

The word generally out of Washington is that President Johnson expects some pretty fast action on Medicare* when the eighty-ninth congress assembles.

Whatever the merits of Medicare, as the politicians have been describing it, they can get out of it perhaps the greatest patronage bonanza since the government got into running the country's farms. A vast array of bureaucrats will be needed to administer it, and, of course, only party faithfuls can qualify.

But what about the old folks who are supposed to benefit? If we believe the politicians, life after 65 will be a breeze — no more doctor bills, no more hospital bills, no more drug costs, no more service costs. Our seniors can have full hospital care, doctors and nurses swarming about to wait on them hand and foot, with free pills and medicine so long as there still is breath in their old carcasses.

It's a wonderful filial thought. Folks who languished through to their 65th birthdays can practically be made over and, with Medicare at hand, outlive Methuselah. In addition, their offspring can furtively gloat that they won't need to chip in for a new set of store teeth, new eyeglasses, or special shoes. Their senior kinsfolk, if we believe the politicians, will actually enjoy being laid up, since the best of everything will be theirs, along with the comforting thought that the government will pick up the whole tab.

Medicare is mainly a hospitalization plan aimed at taking over an exist-

ing free enterprise activity. But it has numerous tricky provisions about hospital care that may cost the old-timer, or his heirs, a lot of money if he doesn't guess right about how long he'll need hospitalization. No matter what his ailment is, he'll have to share a room with others or pay the difference. Any service he needs beyond what the hospital can provide under Medicare, he'll pay for himself.

He'll have to pay his own doctor bill, also the cost of a private or special nurse's services. No matter how small the print seems to be getting in his home town newspaper, Medicare won't provide him with glasses. Nor will it provide store teeth or a cane.

Like all other government "public service" activities, Medicare is strictly a bureaucratic undertaking, relegating to arbitrary officials the decision as to how we should get sick after 65. And the heck with him who can't fit into their schedule!

We might well ponder on what would have happened had Medicare been in force in Methuselah's time!

The Editor's Soliloquy

Therapeutic Meditation

Is reminiscing a contributing factor in the successful adaptation to advancing age? The studies of McMahon and Rudick* indicate that the depressed oldster who does not recall the past dies significantly sooner than the nondepressed one who indulges in retrospective soliloquy. It was even suggested that reminiscing is of therapeutic value and does not necessarily denote senility.

Between the reminiscer and the reminiscee there operates that subtle, psychological mechanism — the personal equation.** Who has not as a child sat enthralled at a grandfather's knee, glimpsed alluring vistas into the past, traversed their full length, dissolving the barriers of space and time, and then and there relived vicariously some magically resurrected incident, tragic or comic, heroic or humble — a never-to-be-forgotten adventure. Perhaps therein lies the secret formula for the special rapport so often felt between the two alternate generations. Surely the rare value and nostalgic charm of such reminiscence cannot be challenged.

Rather than constituting boredom ad nauseam, pleasurable recollections can for both participants be a profitable and intimate sharing of a bygone experience in the warm afterglow that suffuses all memorable past events. It can be a desirable recreation, however, only when indulged in moderately and not to the exclusion of constructive participation in the present and the future; for the oldster has much to contribute to both time dimen-

Curbstone Consultation

Valvular Heart Lesions

QUESTION: How safe is open-heart surgery for valvular heart lesions?

ANSWER: This is a difficult question, but in general the open-heart valvular surgery falls into the reconstructive and replacement types. The mortality and morbidity is of a higher magnitude for operations upon the aortic valve than upon the mitral valve. Mitral valvular surgery of the reconstructed type has a probable over-all mortality of between 10 and 15%. Valvular replacement surgery has a slightly higher mortality in over-all figures. Aortic valvular reconstructive and replacement surgical procedures has a mortality that varies widely from one cardiac center to another. The mortality figures range from as low as 10% to as high as 50%. It is, therefore, difficult to pick an average figure, but certainly the mortality must range from 25 to 30% as an average over a long series of cases at the present time. In part, the mortality is not due to the surgical procedure itself, but to complications in the cardiopulmonary and renal systems. Also the status of left ventricular myocardium in aortic valvular disease may be much more compromised than in mitral valvular disease. In all fairness to the surgeon one must equilibrate the prognosis of patients with severe aortic and mitral valvular disease in terms of longevity and invalidism as compared to the postoperative status especially in prosthetic valvular replacements of those patients who survived the procedure. Although experience has not been long in terms of years, it has been sufficient to indicate that individuals who survive resume fairly normal lives.

Bacteriology of Bronchitis

QUESTION: Do you think the sensitivity studies of the coughed-up specimens are satisfactory as a guide for effective antibiotic therapy?

ANSWER: We have long felt that a bronchoscopic specimen yields more valid bacteriologic data than a coughed-up specimen contaminated with mouth organisms. If bronchoscopy is not possible, the best alternative would be either tracheal aspiration or the collection of a specimen of coughed-up sputum at the bedside so that the physician could be reasonably sure that the specimen came directly from the bronchial tree and was sent to the laboratory promptly, as are the bronchial secretions collected at bronchoscopy.

MILTRATE®

meprobamate 200 mg. + pentaerythritol tetranitrate 10 mg.

Effective tranquilization
plus
long-acting coronary vasodilation
for
prophylaxis of pain in angina pectoris

Indications: 'Miltrate' is useful for prophylaxis of pain in angina pectoris and coronary insufficiency, especially where anxiety is a factor. **Contraindications:** Like all nitrates, pentaerythritol tetranitrate should be avoided or prescribed cautiously for patients with glaucoma. Previous allergic or idiosyncratic reactions to meprobamate contraindicate subsequent use. **Precautions:** *Meprobamate* — Patients engaged in activities requiring alertness should be warned of drowsiness. Meprobamate may increase the effects of excessive alcohol, and the possibility of dependence should be considered, particularly in patients with a history of drug or alcohol addiction. Sudden withdrawal may result in reactions, rarely epileptiform seizures. Grand mal attacks may be precipitated in persons susceptible to both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies. **Side effects:** *Pentaerythritol tetranitrate* — The most common side effects are transient headache, nausea, and rash. Weakness, palpitation, flushing, gastrointestinal distress, and lightheadedness have been reported on a few occasions. *Meprobamate* — May cause drowsiness and, rarely, ataxia, usually controlled by decreasing the dosage. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses of the drug. Mild reactions include urticarial or maculopapular rash. Serious reactions, rarely encountered, include dermatological effects, acute nonthrombocytopenic purpura, chills, fever, fainting spells, angioneurotic edema, bronchial spasm, hypotensive crisis, anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic, and the drug not be reinstituted. **Dosage:** Usual dosage is one or two tablets before meals and at bedtime. Individualization of dosage is required for maximum therapeutic effect. Doses above twelve tablets daily are not recommended. **Supplied:** White tablets, each containing meprobamate 200 mg. and pentaerythritol tetranitrate 10 mg. ***Before prescribing, consult package circular.***

WALLACE LABORATORIES / Cranbury, N. J.

CML-4087

Fracture–Trauma Conference

Regional Anesthesia in Children with Extremity Injuries

The anesthetic management of children with fractures can sometimes pose more dilemmas and problems than the surgical management. This is particularly true in the case of the child with a full stomach and a recently fractured extremity. In order to illustrate the important points of management, it will be more meaningful to describe the usual practice of one center rather than to describe one case; for one anesthetic success is not evidence of anything except, perhaps, a certain degree of luck.

Early reduction of a fractured arm in a child with a full stomach can be accomplished safely only with a regional anesthetic. The vomiting and aspiration associated with general anesthesia are a leading cause of anesthetic deaths in children and must be avoided. One must choose, therefore, whether to perform a regional block at once or to wait for the stomach to empty and use a general anesthetic. Our practice is to rely on a regional anesthetic and immediate reduction.

Prerequisites for Success

1. Adequate premedication at least thirty minutes before the block is attempted. Secobarbital 1 mg. per pound plus meperidine 0.5 mg. per pound of body weight given intramuscularly is usually adequate.
2. A calm, unhurried atmosphere.
3. Precise technique with proper equipment.

Children of all ages will accept a brachial plexus block if they are well premedicated and gently approached. The intended procedure must be described as part of the treatment that "will make the arm well." The child with a fresh fracture will, in fact, accept the block more readily than a child coming for elective surgery. He is anxious to have the arm fixed and the pain stopped. He looks to the doctors for help and will usually accept the needle as part of the treatment.

Axillary or Supraclavicular Approach

Drugs of choice are lidocaine 1 percent, to which may be added tetracaine to make a 0.1 percent concentration if a prolonged effect is required. Either the axillary or supraclavicular approach can be used. Performing the block

Continued

by the axillary approach causes the patient less discomfort because one need not elicit a paresthesia in order to find the nerves, as is necessary with the supraclavicular approach. However, the supraclavicular block is more reliable, lasts longer and produces a more profound anesthesia. The choice of the approach will, therefore, be influenced by the requirements of the surgeon and the experience and preference of the anesthesiologist.

Finally, after the block is performed, everyone should be prepared to wait for the anesthetic to take effect. There is no escape from this. To try prematurely to reduce a fracture will cause the patient to lose faith in the block. If the child is once hurt by the manipulation, he will tend to interpret all sensations, such as pressure and pulling as painful. Additional doses of a narcotic or thiopental can be judiciously used if the patient is still apprehensive, but sedation should stop short of depressing the laryngeal reflexes.

Advantages and Complications

The advantages of this method are that it avoids three major causes of anesthetic deaths in children, i.e., hypoxia, toxic depression of the cardiovascular system by general anesthetic agents, and vomiting with aspiration.[1] The main complication of a brachial block is a toxic reaction from the local anesthetic agent. This can be avoided by limiting the amount of drug to the maximum safe dose and by avoiding intravenous injections. The incidence of pneumothorax following supraclavicular brachial plexus block has been reported as 0.66 percent and 2 percent.[2] Separate figures for children are not available, but in our experience with children it has been a rare occurrence. The incidence of postanesthetic neuropathy due to the block is also extremely small and is not a significant factor in the choice of an anesthetic.

Tumor Conference

Problems in Diagnosis and Management in Carcinoma of the Bile Ducts

When a patient develops jaundice of an obstructive nature, the physician is often presented with a difficult diagnostic problem and a therapeutic challenge, as evidenced by the following case report:

Case History

A 39-year-old white female entered the University of Minnesota Hospitals for the first time on June 19, 1964, with a chief complaint of progressive painless jaundice of one-month duration. Two years prior to admission (April 1962) the patient underwent the first of five operative procedures for a similar complaint. *At that procedure, a firm mass was palpated in the hilum of the liver at the bifurcation of the common duct.* This tumor resulted in obstruction of the right hepatic duct, but the left hepatic duct remained patent. A long limb #10 T tube was inserted into the left duct, the obstructing mass biopsied and a cholecystectomy performed. Pathologic examination revealed chronic cholecystitis with cholelithiasis, and the mass was interpreted as showing ectopic islands of biliary mucosa in dense inflammatory fibrous tissue. It was thought to be inflammatory reaction and not malignant.

Second Operation

The patient apparently improved for a short period on continual bile drainage and was re-explored on August 3, 1962, with the plan to resect the mass. The hilar tumor had, however, enlarged and extended into the right lobe of the liver and was considered at that operation to be unresectable. By this time the left hepatic duct appeared to be invaded, but could be dissected free. A portion of the duct was resected and an end-to-end anastomosis was made to the common duct over a multi-perforated #10 catheter. *Again biopsy was interpreted as ectopic biliary mucosa.* The patient suffered general malaise following this procedure and in March, 1963, developed chills and fever, without evidence of increased jaundice.

Third Operation

After a brief course of antibiotics she improved, and on March 21, 1963, she was re-explored for the third time, again contemplating resection of the tumor mass because malignant diagnosis had not yet been reported. Dissection in the hilum of the liver revealed no extra or intrahepatic duct on the right side even after resection of the tumor high into the liver parenchyma. A cannula was again threaded into the left duct and fixed in place for total biliary drainage. Histologic interpretation of the resected specimen for the first time was reported as a *well differentiated adenocarcinoma.*

Fourth Operation

The left hepatic-duct biliary diversion allowed the patient to remain well until September, a period of six months, at which time the drainage tube was accidentally removed. Jaundice with pruritis ensued, and on November 1, 1963, the patient underwent her fourth surgical exploration. The tumor had recurred locally, had attained a

Continued

size of 2 x 3 cm., and had invaded the duodenal wall and peripancreatic region. Enbloc resection was performed, requiring removal of a portion of the wall of the duodenum. At this time, both bile ducts were located and a limb of a Y tube was placed in each duct. The long limb was placed into the duodenum and the duodenum sutured to the liver capsule around the hilum. The T tube was brought out through the separate opening in the duodenum for external drainage. At the time of this operation, the patient was in her fifth month of pregnancy. Postoperatively she improved and in March, 1964, underwent a spontaneous normal delivery.

Fifth Operation

In June, 1964, she was admitted for the first time to the University of Minnesota Hospitals. By this time, bile drainage had quantitatively decreased, jaundice had progressed, there had been a six-pound weight loss, and melena was present. When examined, she was cachectic and pale, and her liver was palpable 4 cm. below the right costal margin. Her hemoglobin was 3.8 gm. Preoperative bilirubin ranged as high as 32 mg. total, 18 mg. direct, and alkaline phosphatase was 82 King-Armstrong units. Fecal urobilinogen was 12 Ehrlich units per cent. Cholangiograms through the T tube demonstrated no patency of the biliary tree.

On June 29, after a series of transfusions had raised her hemoglobin to 13 grams, she underwent her fifth operation. The tumor had recurred locally and attained a size of 4 x 5 cm. It firmly surrounded the portal vein and the hepatic artery and had extended high into the liver hilum. After dissecting free the previous duodenal hepatic anastomosis, it became apparent that the total extrahepatic biliary duct system was obstructed with tumor mass. The left lobe of the liver was cut across, and a dilated intrahepatic biliary duct 1.5 cm. in diameter was identified. This was cannulated, and an operative cholangiogram demonstrated the dilated ducts in that lobe and confirmed the total duct obstruction at the hilum. The left lobe of the liver was then further incised until a duct 5 mm. in diameter was found, and a Roux-y hepatojejunostomy was performed. Postoperatively her course was very smooth, her bilirubin decreased to 12.3 mg. total, 5.7 mg. direct, and her alkaline phosphatase decreased to 58 King Armstrong units. At the time of this report she is four months postoperative, maintaining full household activities, is pain-free, and has gained four pounds. She has just begun a course of X-ray therapy to the liver area with hope of further palliation. Her hemoglobin has remained in the normal range and her bilirubin is at present 4.9 mg. total, 2.4 direct.

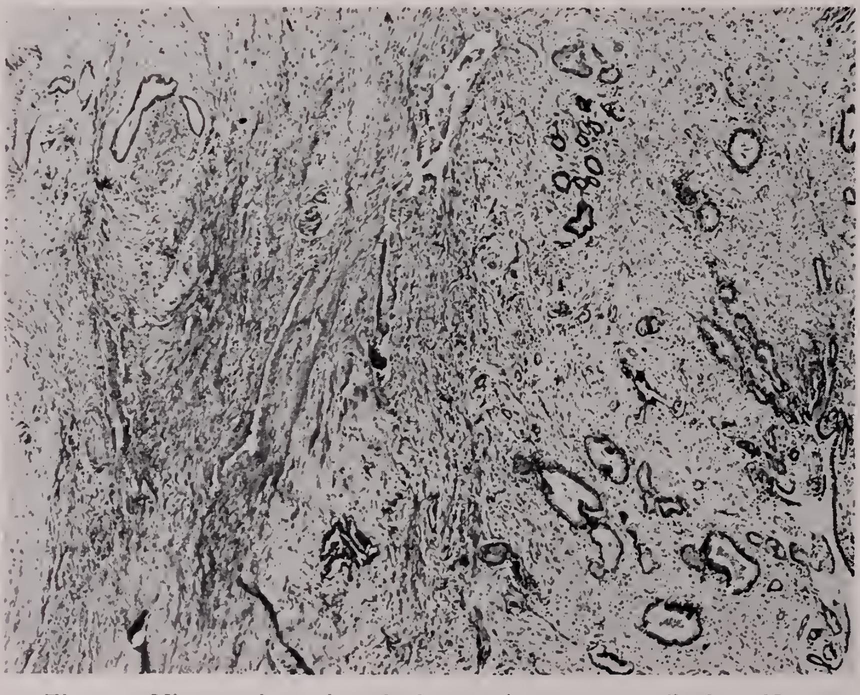

Fig. 1 — Microscopic section of adenocarcinoma of the bile duct. Note the well differentiated glandular structure. Also note the perineural infiltration in the upper left corner of the section. (Microscopic section times 40).

Discussion

Cancer of the extrahepatic biliary tree surprisingly accounts for about 6,000 deaths per year in the United States.[7] In various autopsy series it is reported to appear in 2.6 to 4.5 persons per thousand consecutive autopsies. Glenn has reported that three per cent of all cancer in the United States is in the extrahepatic biliary system.[1] In the Mayo Clinic series, the tumor is reported to be present in one of every 210 biliary duct operations.[6] The incidence is most prevalent in the fifth and sixth decades and does not seem to have a marked sex preference. Cases have been reported in the second decade of life.[3]

Symptoms

The initial symptoms of painless jaundice in this patient are quite typical. Symptoms of acute cholangitis do occur, but often, as in this case, only after surgical intervention. Pain does occur in about one-half recorded cases, though it often develops after the onset of jaundice. Marked weight loss frequently out of proportion to the degree or duration of associated symptoms is commonly present, though not exhibited in this case. The severe anemia present in this case is probably due to bleeding from the biliary tree as melena was present. Evidence of enteric bleeding, however, is frequently not present to explain the anemia seen in many cases of carcinoma of the biliary tree. Associated cholelithiasis is present in up to 40 per cent of cases.[10]

Pathology

Grossly, the tumor often appears, as in this case, in the form of diffuse scarred mass in a porta hepatis, though it may be papillary or nodular. Histologically, the tumor only infrequently appears as well differentiated glands, but most often is seen as papillary or undifferentiated adenocarcinoma.[8] The presence of well differentiated glands in juxtaposition to the biliary tree should immediately alert the surgeon to the possible presence of malignancy. Perineural involvement is pathogneumonic and every attempt should be made to demonstrate this finding.

Prognosis

The prognosis of cancer of the bile ducts is indeed very poor. The hope for prolonged survival lies in early diagnosis and radical surgery, especially in the differentiated type. Unfortunately, in the majority of cases the tumor is beyond resection for cure because of local extension into the porta hepatis and the liver parenchyma. Forty-five to seventy-five per cent have distant metastases at initial laparotomy despite a short history of preoperative symptoms.[2,9]

The first local excision with primary anastomosis was done by W. J. Mayo in 1903. Few local procedures such as this have been carried out, for in more than 74 per cent of the cases the tumor lies in such a position that no duct is available above the tumor for anastomosis.[6] A radical resection, described by Whipple in 1935 for tumors involving the duct more distally, has offered some hope in such cases. In a study of 172 cases, however, Sako reported the average survival was only 4.2 months.[8]

Continued

Treatment

The surgeon, therefore, must resort to palliative procedures in most instances. Tube drainage usually offers short term relief as exhibited by the several procedures attempted on the patient reported. The hepato-enterostomy which offered this patient her most comfortable existence was described in 1905 by Kehr and perfected by Longmire in 1954.[5] The use of this procedure allows enough bile product clearance to prevent itching and maintain fat breakdown for nutrition. Five of seven patients recently reported by Kulmeyer have met with similar success, but the long-term follow-up of these cases, as in ours, is not yet available.[4] Antacid should be given to the patients for prevention of the so-called Mann-Williamson type ulcer syndrome present with bile and pancreatic juice deviation from the stomach.

Neurological Conference

Multiple Sclerosis*

Dr. Robert Soll**

The conference today concerns a patient with multiple sclerosis. This is a crippling disease which has its onset relatively early in life, often at the beginning of a person's productive career. The very name, multiple sclerosis, is one that carries an ominous forboding for many people because of the relentless exacerbations that usually follow a transient improvement, leaving the patient in even greater frustration and disability than before. The disease begins insidiously, often with a minor episode of limited paralysis or paresthesia of an extremity, or a visual disturbance. Frequently, after a comparatively short time, the patient begins to develop a weakness and stiffness of the lower extremities; or he may complain of a heaviness or numbness of his legs. He may note an increased urgency to urinate, and on occasion, he may be actually incontinent. Subsequently there may be a variable period of time, perhaps months, when the patient finds himself apparently in perfect health before again noting the reappearance of an unsteadiness in gait, due not only to weakness but also to imbalance. He may note a trembling of his hands, particularly on intentional movements. His speech may develop a slurred quality when long words are spoken. There may be slight choking on attempting to swallow liquids. The hands and feet may continue to "feel," but there is present a peculiar quality of numbness which the patient often has difficulty in describing. As the disease progresses, the patient finds that he is unable to continue gainful employment; medical costs mount, with resulting problems in maintaining his living conditions.

I'd like to call upon Dr. Olson at this point to give a brief historical account of this patient's illness.

Dr. Byron Olson***

The patient is a 43-year-old single, unemployed clerical worker with symptoms resulting from her demyelinating disease extending over the

Continued

past four years. A few months prior to the onset of her illness, she had a period of severe chest pains, a pleurodynia-like syndrome for which she did not see a doctor. The first symptoms relating to her disease were numbness in her right arm and leg and an associated feeling of awkwardness during September 1960. This condition gradually improved over one month's time. Three months later, in December 1960, she developed decreased vision in her right eye. The only objective neurological finding at that time was temporal pallor of the right optic disc. Intramuscular ACTH therapy was given and was followed by some improvement. Her visual complaints subsequently continued with varying degrees of severity during the following year and a half.

In May 1962, she was hospitalized for severe impairment of vision in the left eye which did not respond to ACTH therapy. Later that year, she participated for six months in a secretarial course at the Sister Kenny Institute. Unfortunately, her typing improved only very slowly, due to mild inco-ordination. The working diagnosis at that time was demyelinating disease of unknown cause with some degree of psychogenic overlay. In December 1963, three years after the onset of her first symptoms, she was admitted to University Hospitals following a one-week history of numbness and awkwardness in the left arm and leg, plus blurred vision in the right eye. Physical examination revealed unsustained ankle clonus bilaterally and temporal pallor in both optic discs. Her gait was somewhat unsteady at that time. A ten-day course of intravenous ACTH therapy produced moderate subjective improvement. She was followed in the outpatient clinic over the subsequent nine months until early September 1964.

Of particular interest were her complaints of persistent daily nausea and vomiting during the early morning hours, only partially relieved by compazine or tigan. Intramuscular ACTH and a short course of Vitamin B_{12} were given regularly by a visiting public health nurse. The patient was again admitted to the University of Minnesota Hospitals on September 8, 1964, from the emergency room, after one week of increasing ataxia, vertigo, blurred vision and right-sided numbness, and after falling four to five times on the previous day. She slowly improved with intravenous ACTH therapy and was discharged to a nursing home, walking with some difficulty unassisted.

Her past history was unremarkable except for a 15-year history of occasional severe left-sided headaches which promote nausea and vomiting unless Empirin #3 tablets are taken promptly at the onset.

Physical examination during her recent hospitalization was unremarkable except for the neurological findings. She was a moderately well developed, thin, white female, prematurely gray, and variably co-operative. Her optic discs revealed marked temporal pallor bilaterally. The deep tendon reflexes were hyperactive in the lower extremities and there were positive toe signs bilaterally. There was decreased co-ordination and some tremor, both more marked in the right arm and leg. Subjective sensory signs were of questionable validity.

Dr. Soll

We have two particular problems with such patients: Financially they find it very difficult to continue private medical care because they are unable to maintain employment. Psychologically they need the consistent, empathetic care which their own private physician can offer them. Secondly, there is the problem of medical treatment itself. I would like to discuss the treatment that has gained the greatest acceptance up to the present. To begin our discussion I would like to ask Dr. Brantner about his psychological evaluation of the patient and her attitude toward her illness.

Dr. John Brantner*

The patient could be described as unco-operative as far as testing was concerned. I felt that any immediate administration of standard tests was going to yield completely unreliable results. The Peabody wide-range vocabulary test is used to evaluate severely handicapped people. The patient has an IQ of about 125, college-level intelligence. Brain damage tests were negative. There was no sign of central nervous system involvement. She does not show deterioration of thinking. A multiphasic test taken a month previously, showed depression, anxiety, discouragement, unhappiness, social withdrawal, and introversion. I spent much of the interview time chatting with her, attempting to get a better idea as to what kind of a person she was. She dresses well and appears considerably younger than her age. She was a likable individual and a very interesting one: intelligent and charming; but she quite rapidly erects a barrier between herself and other people. It is as though she is saying quite directly, "You are well and I am not. You have a future to look forward to; I do not. My plans have come to nothing; I am not able to be a secretary. Although I have been interested in art much of my life, I cannot draw. I cannot walk. All of my plans have come to nothing; therefore, there is no point in my going to see a doctor, for the doctors can do nothing." She resents the normal pleasantries in which one might indulge, and becomes somewhat angry at other people, saying in effect, "You can laugh; I have nothing to laugh about." At one time in her life, she wanted to be a commercial artist, but she is no longer much interested. As we were talking about other things, she drew a couple of lines and instantly made a fairly impressive sketch.

I can say with confidence that she is very intelligent, that she doesn't show psychological signs at all of central nervous system involvement or deterioration as a result of her disease, but that she is depressed, discouraged, unhappy, and unwilling to do anything about it at the present time. I was surprised to note that the disease was so relatively recent. Her attitude may, therefore, represent a more basic personality characteristic than a reaction to her disease.

Miss Helen Kretchmer**

At the time of the original referral the patient was having difficulty in walking and with balance. Her mother assisted her in maintaining her small apartment and probably did her cooking. The patient's father was an 8th grade graduate and worked as a machinist. He was ill with a heart condition in 1944, became very confused, and was cared for in a nursing home, and at home. The family was never on relief, due to the efforts of the children in contributing to the family finances and to the mother's working.

The patient had been a premature baby. Her mother had considered her frail from birth although she was not slow in developing. Both the patient's

---

*Clinical psychologist, University of Minnesota Medical Center.

**Supervisor and assistant professor of social service, University of Minnesota Medical Center.

Continued

mother and the patient herself had the idea that she was a very weak person. This has seemed to influence the mother's treatment of her. The mother appeared to feel guilty about the patient's developing a demyelinating disease. I think this agrees with what Dr. Brantner has suggested — that possibly her discouraged attitude developed at a much earlier age and is not due to her present condition.

The patient graduated from high school and did well, although she was often out of school with illness. She was especially good in art and attended the Art Institute where she took drafting. She used her drafting experience at the Northern Ordnance during the war. She also did office work for different insurance companies. She changed jobs frequently. She was always somewhat withdrawn and found it difficult to be close to people. Nevertheless, her mother states that she had many friends and went out a great deal prior to development of her illness. After that time her personality changed; she did not want her friends to see her, and she felt that people would not want to associate with her.

At the present time she depends on her mother for personal assistance but does not wish to live in the same home with her. She had previously moved to within one block of her mother so that she could have more help. She would probably be best satisfied living in an apartment next door to her mother, so that she could retain independence. She does not have the money to pay for a private doctor, although I think she would be very well-suited to having a private doctor, as she does need continuity in care. The mother will remain a strong factor in her plans. In a guarded way, the patient has recently expressed great dissatisfaction with the nursing home in which she has been placed, but actually she now seems to be doing better physically. It is quite possible that she may be helped to lead a more normal life in a semiprotected boarding home placement near her mother. As far as her returning to work is concerned, I don't think that she would be able to hold a job.

Mrs. Shimamoto*

I would like to tell about the apartment in which she lived, where she was listed under an assumed name. She liked this apartment; in fact, she didn't want to move. When she applied for relief to pay the rent, the stipulation was that the landlord also was to make application to relief for payment. I am not familiar with the procedures, but he did not do so, and finally she was evicted. Her apartment was on the third floor facing the auditorium construction, where drilling started at 5:30 in the morning and continued until 11:00 at night. This was all she talked about when I visited at 8:00 a.m. She was quite unhappy and wanted to move near to her mother who was coming every day to help her.

Dr. Richard Foreman**

The patient said she went to her mother's to eat, but actually the mother went to the patient's apartment to prepare the meals. The patient stated that her mother could give her considerable help; but the mother really can't be expected to give her daughter much nursing care.

---

*Public health nurse, Minneapolis Health Department Visiting Nurse Service.

**Chief resident of neurology and medical fellow specialist, University of Minnesota Medical Center.

Dr. Soll

The patient has been very independent most of her life. When she can't be independent, she is embarrassed. She has always paid her bills herself; now she can't pay them because she can't work. I think this is an extremely important aspect of this case. Is she a person who outwardly wants to appear independent, but actually has a great emotional as well as physical dependency on others?

Dr. Brantner

She does tend to reject people. Living alone is very important to her, but she recognizes that she can not possibly be an independent person, and this of course contributes to her condition.

Dr. Richard Magraw*

An illness of this type can put many things in different perspective. A person may continue through life with expectations that tomorrow he will start 'cashing in' on the good things of life, so to speak; then, if he has a heart attack, multiple sclerosis, or some other disabling disease, he will really be caught short in reaching fulfillment. This type of experience is an almost universal one in life and usually goes by the name of involutional reaction. I am not saying that this is what our patient has, but I think there are other illnesses with this same type of emotional reaction which she seems to have.

At this point in the conference, the patient was brought into the room for questioning.

Dr. Soll

(To the patient) I'd like to ask you what you feel are the prospects of your going back to work?

Patient

I don't think I could do it. I might be able to do a part-time job if it were very easy, otherwise I couldn't. I have nausea when I get up in the morning; it usually lasts most of the day unless I take something.

Dr. Soll: Are you getting around fairly well now, as far as walking is concerned?

Patient: Yes, I can walk pretty good. I have to watch so that I don't fall. I can't walk very fast.

Dr. Soll: Is your walking better than it was when you came into the hospital?

Patient: Yes, when I came in I was staggering so. I walked in but I don't think I could have walked out. I had poor co-ordination. I couldn't make my hands wash a dish and put it down. It seems simple but I couldn't make my hands do this.

Dr. Soll: What have doctors told you in the past as to what to expect from this condition?

Patient: Not a thing.

---

*Director, Comprehensive Clinic Program, University of Minnesota Medical Center.

Continued

Dr. Soll: They haven't told you anything about understanding your illness?

Patient: Not that I can remember, no.

Dr. Soll: What do you think of your condition?

Patient: I think eventually I am going to be much worse off than I am now. I am not looking forward to it.

Dr. Soll: Would you hold your hands out for us? Is the sensation in your hands different from what it used to be?

Patient: One hand does feel different. It seems weaker —

Dr. Brantner: Are you still in the nursing home?

Patient: Yes.

Dr. Brantner: How do you pass the time?

Patient: Sleeping.

Dr. Soll: Do you read or watch TV?

Patient: The TV doesn't look very good. The picture isn't good, and I don't think it is ever going to be because of my left eye. Things aren't perfect in the other eye either. My glasses can't be changed because I can't see the biggest letters anymore, so the picture on the TV doesn't look very good. I am not very happy. I want to be by myself.

Dr. Brantner

Would you prefer not being by yourself?

Patient

I prefer living alone. My mother lives only a block away and I can eat there every day. As far as that goes, she gets both our groceries delivered by the same grocery store. My mother usually has so many grandchildren to visit her that I can go over there to amuse myself. I used to like to go dancing, but I haven't been able to dance for about two years.

Dr. Brantner

Have you done anything about taking up painting again?

Patient

No, I can't do it. My sight isn't too good, and I can't tell the colors. I tried this a long time ago. I even quit work for six weeks to go to art school. You have to have quite a good education. An awful lot of people are interested in art, and it is hard to get into. I couldn't work and go to school. How would I pay for it? That's the problem. I could do a certain amount of sketching, but it wouldn't be as good as it was. I'd like to go to night school because there are all kinds of people from different walks of life.

There being no further questions, the patient was escorted from the room.

Dr. Foreman

I think I am the only one here who has had any personal contact with the patient in the ward situation during her hospitalization. We were not surprised that Dr. Brantner found her intelligence quite high. She is a very bright person, but it was also perfectly obvious to us that she did have organic involvement of the nervous system. She erects a wall between herself and the physicians. When visiting her during ward rounds, one could never converse with her, because she would lie in bed and wouldn't answer. If she did answer, frequently it was to make a hostile remark. On the other hand, it became apparent that she could do much more for herself than one would expect. She was seen by members of the staff to walk perfectly well with only a mild disability, whereas in objective testings she would stagger against walls, almost falling down. She probably had the actual capacity to do more than she did. The other thing was her extreme desire for independence. She definitely was not going to go anyplace but home, to a third floor apartment, in spite of the fact that when we met with her superficially, she could hardly feed herself or go to the bathroom unassisted. We did feel she could get along at a boarding home, and I am glad to hear that this suggestion has been made. She walked much better while in her room than she did at any other time in the hospital. So I think she gets along quite well physically.

Dr. Soll

It was apparent to me while checking her reflexes that the upper extremities were considerably less hyperactive than the lower. This finding is common in multiple sclerosis and demonstrates a correlation between the pathological process of the disease and the clinical picture. We have here a disease in which there is a multitude of lesions at random throughout the whole nervous system. The fact that her upper extremities are considerably less involved than her lower extremities is simply because there is less distance between the arms and the brain than there is between the legs and the brain; in other words, there are quantitatively more lesions within the whole spinal cord than in part of it. Thus a totally greater number of fibers to the leg are interrupted than to the arm. This is primarily the reason why multiple sclerosis patients have a much greater involvement in the lower extremities than in the upper.

Etiology

Attempts have been made to solve the dilemma of etiology, and thus unlock the key to its logical treatment. The possibility of an infectious cause has been repeatedly suspected, particularly by specific infecting agents such as viruses, bacteria, or even spirochetes. At no time has any evidence approaching conclusive proof been offered that an infectious agent was directly responsible. Faulty mineral metabolism, injury, heavy metal poisoning, alterations in the coagulability of the blood, and diet have also been suggested as possible factors. Heredity certainly may play a role; however, its significance cannot be denied in a great many diseases. Finally, an immunological relationship has been suggested, and here the evidence, although circumstantial, is impressive. We know that nervous tissue is potentially antigenic. Experimentally, central nervous tissue can incite an encephalomyelitis even when it is derived from the same animal. In addition, one can produce an exacerbating and remitting disease in guinea pigs using central nervous tissue as the antigen. The course is not unlike that of multiple sclerosis which we observe clinically. Experimental allergic encephalomyelitis has been closely allied etiologically with the immune mechanism. A significant percentage of multiple sclerosis patients have been found to have antibrain antibodies in their serum, far in excess of other neurological conditions in which central nervous system damage

Continued

is also present. Pathologically, a similar perivascular cuffing of mononuclear cells is found within areas of the central nervous system, correlating with the demyelination in multiple sclerosis as well as in the experimentally produced encephalomyelitis.

Treatment

The use of ACTH in multiple sclerosis is the only method of treatment which has continued to be used over the past decade without dropping into disrepute. Since steroid therapy is well known for its use in allergic inflammatory conditions, the probability that its anti-inflammatory action contributes to the improvement of multiple sclerosis patients is great.

Assuming that multiple sclerosis is an autoimmune disease, it becomes exceedingly important to emphasize that an exacerbation of multiple sclerosis is as much a medical emergency as an acute attack of rheumatic fever or lupus erythematosus. The inflammatory reaction, found within the brain and spinal cord of acute multiple sclerosis, is causing damage, and the more quickly this is aborted, the less will be the functional deterioration of the patient. It is common that recovery following an exacerbation of multiple sclerosis leaves the patient less functional than before the attack. Therefore, rapid institution of therapy at the first sign of deterioration in a patient's condition is necessary. A doctor should instruct multiple sclerosis patients not to hesitate to inform him of any change in their condition that could imply another attack, regardless of how subtle the changes might be.

Our standard method of therapy at the University of Minnesota is to administer ACTH, either 40 or 60 units in 1000 ml. or 5% D/W over an eight-hour period for ten consecutive days. Histamine may be added to the intraveonus solution if desired at dosage of 2.75 mg./1000 ml. The patient is placed on a low-salt diet and an anticholinergic agent is used to decrease the possibility of gastric hyperacidity. Empirically the diet is supplemented by a high intake of vitamin B complex and C. Following the 10-day course of ACTH, steroid therapy may be tapered off, using decreasing increments of ACTH gel over the next 10 days; however, this is optional. Although side effects from ACTH therapy are not frequent, those that do occur are euphoria, psychoses, acne, edema, and GI bleeding. Usually side effects result during prolonged administration of ACTH. I would like to mention, finally, the common occurrence of rapid deterioration in a patient's condition during a febrile intercurrent infection. These infections should be treated promptly with appropriate antibiotic therapy. Here again, it is the duty of the physician to instruct the patient accordingly.

Dr. Magraw

About a year ago, Dr. George Thorn reported the idea of administering large doses of steroid every other day to avoid dampening the pituitary ACTH production.

Dr. Foreman

We haven't done studies on steroid excretion in patients receiving ACTH therapy. On the other hand we treat a great deal of multiple sclerosis using the schedule that Dr. Soll has outlined. To my knowledge no instances of withdrawal symptoms or symptoms of hypopituitarism have occurred after this type of regimen. Only rarely do we administer ACTH intramuscularly, following this 10-day course of intravenous therapy.

Dr. Soll

Some clinicians keep patients on ACTH for a considerable period of time. I do not believe, however, that prolonged administration is necessary. Once the acute process subsides, one can withdraw ACTH. A spontaneous clinical remission that would have occurred eventually is simply hastened by the ACTH; therefore, it wouldn't be necessary to continue prolonged use of the drug. Physiologically, I think this is better for the patient, so that he doesn't become completely dependent on ACTH. Of course it would again be instituted upon the next exacerbation of the disease.

Dr. Magraw

Do you think that anyone who gets multiple sclerosis proceeds inexorably downhill? Let me explain the background of my question. I've seen a number of people during my medical career who have very good findings for multiple sclerosis, two of whom have shown no progression during the past 20 years. I wonder whether you feel that there are more forms of this disease or is it sometimes just called by another name?

Dr. Soll

I think that multiple sclerosis has a wide spectrum of clinical forms. On the one hand there is postinfectious encephalomyelitis in which there is usually just one devastating attack. Then there are all degrees of multiple sclerosis, both acute, severe types as well as chronic, slowly progressive types. Finally, a condition such as Guillain-Barre syndrome may be on the other end of the scale, in which recovery usually occurs.

Dr. Foreman

It is possible that many patients at some time in their life may have pathological changes which would be indistinguishable from multiple sclerosis, symptoms of the illness occurring only once and never recurring? Possibly the percentage of these patients is much more common than the type of patients that have been diagnosed as having multiple sclerosis.

Vertigo in a teenager, or a transient episode of numbness or weakness in an extremity, which subsequently clears, are examples. Until we find a way of diagnosing multiple sclerosis absolutely, that is, finding the etiology and conducting appropriate laboratory tests, we have to make the diagnosis on clinical grounds. A good example is the clinical diagnosis of polio; there is a very set clinical syndrome which constitutes polio. When the cause of polio was discovered, the clinical syndromes included under the diagnosis of polio broadened tremendously and many disorders that would not previously have been called polio, came to be recognized as polio. Now multiple sclerosis may be much the same kind of thing.

Dr. Magraw

Dr. Kress, who is in private medical practice in Montana, is visiting us

Continued

at the University Medical Center. I would like to ask him what perspectives he has on multiple sclerosis from his practice of internal medicine?

Dr. Jackson Kress*

As doctors, we like to feel we are doing some good. If we can't, we have a feeling of inadequacy. I think a similar example is the treatment of a cancer patient. When I was younger, I didn't know what to do about it, but now that I am older, one thing I know that I can do is give a patient some kind of support. I think it takes many years to acquire this ability.

Dr. Richard Foreman

Of course as neurologists, we are faced with a great many disorders in which there is no specific cure; so we are much more aware of the necessity of finding other ways to help the patient in the form of support, social planning, and the providing of special equipment to help him function better with his disability. It is really a joy to help a multiple sclerosis patient in these ways. You know you can't do anything specific to reverse the disease process, but there is a tremendous amount of support these people need and can have if the physician focuses on this aspect of the problem. Such patients can be managed for many years in the home situation, if they receive sympathetic care.

Dr. Brantner

This is a patient whose problems are not entirely and solely medical, but of a social nature as well. She also has serious economic problems: living, for instance, on $1104 per year. In addition, she has personality problems which probably existed before but were not brought to anybody's attention. Now the attack on these personality problems might be more validly approached than before she became so disabled.

Robert Soll, M.D.
Neurologist
University of Minnesota
Medical Center

Infections of the Urinary Tract

Part II — Some Microbiologic Considerations*

WILLIAM J. MARTIN, M.D.**
RICHARD D. WAGONER, M.D.**
Rochester, Minnesota

Collection of Specimen

Attempts should be made to secure information about the patient's urinary status with the least amount of manipulation of or disturbance to the urinary tract. Catheterization is not necessary as a routine procedure in the microbiologic study of the urine in males; examination of a second-glass specimen is sufficient. In men, the head of the penis is cleaned with cotton that has been moistened with warm water. The patient passes the first part of the specimen into one container, the remainder into a second container or sterile bottle. The first container, which may contain urethral and prostatic secretions and a certain amount of vesical detritus, is discarded. The specimen for microbiologic examination is taken from the second.

In women, although specimens obtained by catheterization continue to be preferred by some urologists, considerable data indicate that in women, too, specimens obtained by the clean-voided technic often may suffice; this avoids obvious physical, psychologic, and infectious hazards.[11-18] In women, the patient or a nurse separates the labia with one hand and with the other wipes the urethral orifice with a pledget of moist cotton. A woman, unable to produce a second-glass specimen while in the lithotomy position, may straddle a low stool on which two basins are placed side by side. She voids into one basin and then into the other. The specimen is taken from the second basin or is caught directly in a sterile bottle. If the bedridden woman is unable to void in the lithotomy position, she can use a commode, or the collection can be made in a container held beneath a regular toilet seat. In some institutions, the vulva, prior to collection of the specimen, is cleansed with two applications of green soap and water, followed by two rinses with sterile distilled water. Also, cleansing of the vulvar region with hexachlorophene has been recommended. Culture of urine obtained from females by the clean-voided technic appears to give false-positive results in less than 15 per cent of specimens.

Percutaneous suprapubic aspiration of the bladder in order to collect urine for culture is rather heroic as a routine procedure.

Immediate Examination or Refrigeration of Specimen

Urine specimens should be studied for bacterial numbers within one hour after passage, or else the sample should be refrigerated, since storage at room temperature permits bacteria to increase significantly and the bacterial count easily may reach 10,000,000 per milliliter in 18 to 24 hours. However, urine that has been kept under constant refrigeration for longer than 24 hours should be discarded, since saprophytic bacteria multiply and cellular elements may dissolve.

Quantitative Cultures

The presence of 100,000 or more bacteria, cultured from 1 ml. of urine, characterizes 95 per cent of specimens of urine passed by patients with urinary infection. Many clinical infections have bacterial counts of 1,000,000 to 10,000,000 organisms per milliliter. Counts of less than 10,000 bacteria per milliliter usually are not significant. It is wise

Continued

---

*See Part I, Minnesota Med., January issue, Page 95.
**Section of Medicine, Mayo Clinic and Mayo Foundation.

to request two quantitative counts of different specimens, if possible, before giving a definite opinion regarding the existence of urinary infection solely on this basis.

Many investigators today believe that, since quantitative culture of the urine appears to be at least 95 per cent reliable, and since the microbiologic correlation between specimens obtained by catheterization and by clean voiding exceeds 85 per cent, catheterization for microbiologic diagnosis also is unnecessary in women patients.

In attempts to quantify bacterial number, liquid culture media such as broth are not used; cultures are made from various dilutions of urine on pour-plates of solid agar, after which the colonies can be counted. In some institutions a streak-plate technic is used. Use of standard volume-calibrated loops for inoculation of the cultures appears to assure more reliable quantitation. One method consists of employing 0.1 ml. of urine, diluted 1:100 and 1:10,000 with sterile isotonic saline, which is then cultured; in addition a loopful of undiluted urine is inoculated into a medium such as thioglycollate for anerobic organisms. A loop with an inside diameter of 1.45 mm. and designed to deliver 0.001 ml. of urine and a loop with a diameter of 4 mm. and designed to deliver 0.01 ml. of urine also have been recommended.

Low counts may be misleading in infections due to organisms which tend to form swarms, clusters or chains, since there is a propensity to form a single colony. Special media may counteract the swarming tendency of protei, but clusters of staphylococci and chains of streptococci may pose difficulty. Misleading low counts also may be encountered with slow-growing organisms such as bacteroides.

Bacteriuria on Direct Examination

Bacteriuria is detected in a considerable number of patients who otherwise appear to have a normal urinary tract; that is, they lack pyuria and urinary symptoms. The simplest way to detect bacteriuria, asymptomatic or otherwise, is to examine an uncentrifuged specimen of urine that is stained by the gram method or by methylene blue. If bacteria are found, the count is taken to be more than 100,000 per milliliter. The intrinsic error in this procedure is said to be less than 20 per cent; the procedure often provides pertinent data prior to quantitative urine culture reports but preferably should be corroborated by them.

In overt urinary infection, examination of a stained specimen of urine allows classification of bacteria found therein into the broad groups of gram-positive and gram-negative organisms. If antimicrobial therapy is initiated on this basis, the patient may be on his way to recovery by the time the results of culture and other microbiologic studies are reported.

Chemodetection of Bacteriuria

Use of such agents as triphenyltetrazolium chloride to detect significant bacteriuria is reported to correlate with microbiologic procedures in more than 80 per cent of cases. The urine to which the chemical agent is added is incubated, and the colored precipitate that is formed by the reduction of the agent by bacterial metabolites indicates significant bacteriuria (100,000 or more organisms per milliliter). In this reaction, the metabolizing bacteria reduce the colorless triphenyltetrazolium chloride to pink or red insoluble triphenylformazan. A similar colorimetric procedure is referred to as the Greiss technic. Positive results with these tests should be confirmed by cultures.

Presence or Absence of Bacteriuria

While bacteriuria on direct or other examination does not, ipso facto, indicate pyelonephritis, the more persistent the bacteriuria, the more likely that pyelonephritis is present. Bacteria isolated from the urinary tract may represent, in addition to urinary infection, (1) histologically deranged kidneys, that is, second invaders, (2) normal urethral organisms, and (3) contaminants.

Failure to find large numbers of bacteria in the urine of a patient with a classic syndrome of urinary infection should raise the question of (1) precultural administration of antibacterial agents, (2) ureteral obstruction, (3) excessive hydration, which may be indicated by low specific gravity of the urine,

(4) a urinary pH of less than 5 which, per se, can produce bacteriostasis, or (5) slow-growing bacteria, such as anaerobic bacteroides organisms, which may require as much as three weeks before cultures reveal growth.

A single negative test for bacteriuria, whatever method is used, does not exclude infection, since organisms may be spilled into the urine only intermittently.

Pathogens

Gram-negative bacteria usually are associated with acute infections, and gram-positive bacteria may be isolated in certain chronic infections. Over-all, however, infection is more commonly due to gram-negative bacilli; of these, Escherichia coli has been most frequent. E. coli, Aerobacter, and Proteus organisms probably account for more than three fourths of all urinary infections. In recent years there may have been a decline in the incidence of infection due to E. coli and a corresponding rise in those due to Klebsiella-Aerobacter, and Proteus organisms. Pseudomonas organisms are most commonly responsible in patients who have urinary instrumentation including indwelling catheterization and in those who have been receiving antibacterial therapy. Other gram-negative bacilli that are infrequently causative include strains of Achromobacter species and organisms belonging to the Mimae group and genus Serratia. Of the gram-positive organisms, Staphylococcus aureus and streptococci, usually Str. faecalis, predominate but in recent years, infections due to these organisms appear to be of decreasing incidence. In a few infections, usually of the acute variety, culture of the blood also is positive.

Epidemiologic studies suggest that some strains of the Enterobacteriacea are associated with infections of the urinary tract more commonly than other strains. Escherichia serotypes 0-1, 0-2, 0-4, 0-6, 0-75, and 0-117 probably are responsible for almost half of the infections due to E. coli. Escherichia serotypes 0-4, 0-6, and 0-75 most likely cause infections in hospitalized patients. The serotype 0-1 may be the most common type responsible for infections in nonhospitalized patients. A high percentage of infections from Klebsiella-Aerobacter organisms are due to capsular types 8, 9, and 10. Of the four strains of Proteus species, Proteus mirabilis appears to be slightly more frequently encountered than vulgaris, while rettgeri and morgani are uncommon.

So-called urea splitters, which may require acidification of the urine for their eradication when certain regimens are employed, include Proteus, Klebsiella-Aerobacter, Pseudomonas, and certain staphylococcal organisms.

If nephrocalcinosis develops in patients with renal tuberculosis, brucellosis, or salmonellosis, secondary bacterial invaders may obscure the underlying process. A paradox in the pathogenesis of nephrocalcinosis is that among its several causes is infection; conversely some workers believe that it follows the use of sulfonamides.

One type of bacteria commonly disappears during treatment of the infection and is replaced by another; this phenomenon of "replacement of pathogens" occurs in about 25 per cent of cases. Infections due to multiple organisms are present in about 10 per cent of cases and usually are indicative of (1) urinary manipulation including catheterization, (2) recent antibacterial therapy, or (3) a complicated or chronic process.

Especially when so-called bacteriostatic or suppressive drugs are used, negative follow-up cultures of the urine should not cause relaxation of scrutiny, since the infection may recur shortly. In the laboratory, with concentrations of drugs unattainable in the body, agents may produce irreversible destruction of bacterial viability or, in other words, a "killing effect" on bacteria. However, the term "bactericidal" is employed to designate drugs that may do so in vivo, that is, drugs that produce a killing effect on bacteria when administered in concentrations that can be tolerated by the host. The bactericidal agents include the penicillins, streptomycin, bacitracin, neomycin, kanamycin, polymyxin B, colistin, ristocetin, cephalothin, and vancomycin. "Bacteriostatic" agents are those whose concentrations in the body are insufficient to kill bacteria; that is, they produce a reversible inhibition of bac-

Continued

terial proliferation. Bacteriostatic agents may be ineffective when used alone, except in acute uncomplicated situations. These agents include the tetracyclines, chloramphenical, erythromycin, novobiocin, triacetyloleandomycin, the sulfonamides, nitrofurantoin, the acidifying agents, methenamine mandelate, and nalidixic acid.

Although the terms "bactericidal" and "bacteriostatic" may not be ideal, there is a need to be familiar with the concept that they identify. Theoretically at least, optimal therapy with bacteriostatic agents probably requires continuous maintenance of adequate concentrations in the body, more so than does treatment with bactericidal drugs, since, after limited exposure to a bacteriostatic agent, bacterial growth is more likely to be resumed. Also, some agents that ordinarily are bactericidal may be only bacteriostatic when administered in less than optimal concentration.

"Sensitivity" Tests

The results of in-vitro bacterial susceptibility tests, while of great help in certain refractory infections and in those due to staphylococci, cannot be taken as dogma, since a bacteriostatic agent may seem to be indicated on this basis, but it may be known empirically that unless a bactericidal effect is obtained, treatment will be ineffective. In infections due to certain organisms, the pathogens invariably are sensitive to a given regimen; hemolytic streptococci remain susceptible to penicillin, enterococci to penicillin-streptomycin, and Pseudomonas organisms to polymyxin B. Experience also may indicate that certain antibacterial agents will be effective, despite bacterial susceptibility tests to the contrary. As an example, in treating some infections due to Proteus and Klebsiella-Aerobacter organisms, we have noticed that despite resistance of the organisms to tetracycline and streptomycin in the laboratory, eradication of the infection has coincided with the clinical use of these agents in many cases.

Empiric knowledge has accumulated sufficiently to indicate that bacterial susceptibility to antibacterial agents need not be determined routinely in acute nonstaphylococcal urinary infections, since they are time-consuming and expensive and may contribute no additional help. When an acute infection (regardless of bacterial etiology) is resistant to therapy in recurrent or chronic infections, susceptibility tests in conjunction with others (including urographic and cystoscopic studies) may prove rewarding. Bacterial susceptibility tests performed by the disk-plate or agar-diffusion method are not as reliable as those done by the tube-broth or cup-plate dilution method.

Pyuria

As aforementioned, pyuria and bacteriuria are not invariably associated. Significant bacteriuria may be present without pyuria, and the presence of pyuria does not necessarily indicate infection. If the presence of pyuria is relied on to indicate infection, the error may vary from 25 to 50 per cent; that is, in a substantial number of patients with pyuria there is no infection. In dehydration, after certain drugs have been used, in women with vaginitis and in men who have had transurethral prostatic resection (among other causes) pyuria is frequent but not reflective of urinary infection.

Clinicopathologic Correlation

Chronic urinary infections are found in about 10 per cent of routine necropsies and in 25 per cent of necropsies on previously hypertensive patients, but ante-mortem diagnosis of such infections is made in a lesser number of cases. At the present time, it is suspected that individuals with asymptomatic bacteriuria may account for this discrepancy among subjects found at necropsy to have unsuspected pyelonephritis. Since about 50 per cent of chronic infections are relatively asymptomatic, about 10 per cent of acute infections lack urinary symptoms, and significant bacteriuria may be present without causing pyuria, it is evident that a sizable percentage of infections may not cause urinary symptoms or abnormal findings on routine urinalysis. Consequently, it is good judgment to search for bacteria in stained specimens of urine from all patients, with or without pyuria or urinary symptoms, before deciding on their urinary status.

Perkins Tractors

Toward the close of the eighteenth century, Elisha Perkins, an American physician, was curing disease right and left with two little, supposedly magnetic, pieces of metal called tractors. He did so well that even George Washington got a pair. After Elisha died, his son took the tractors to England, where he made a great stir and enlisted the support of the nobility. Unfortunately for him, the famous Dr. Haygarth was skeptical. First he held clinics at which he demonstrated how patients lost their pains when the affected parts were stroked with the tractors. Then, when everyone was much impressed, he took out his penknife and cut the supposed magnets in two; they were imitations made of wood. In the reaction that followed, educated England laughed, and Perkins left for home. (Walter C. Alvarez)*

STRESSCAPS B and C vitamins in therapeutic amounts...help the body mobilize defenses during convalescence...aid response to primary therapy. The patient with a severe infection, and many others undergoing physiologic stress, may benefit from STRESSCAPS.

STRESSCAPS® FOR PROFESSIONAL RECOMMENDATION ONLY

Stress Formula Vitamins Lederle

Each capsule contains:

Vitamin B_1 (as Thiamine Mononitrate)	10 mg.
Vitamin B_2 (Riboflavin)	10 mg.
Niacinamide	100 mg.
Vitamin C (Ascorbic Acid)	300 mg.
Vitamin B_6 (Pyridoxine HCl)	2 mg.
Vitamin B_{12} Crystalline	4 mcgm.
Calcium Pantothenate	20 mg.

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 (one month's supply) and 100 (three months' supply).

Grand Rounds

Pheochromocytoma—Pitfalls in Diagnosis*

Pheochromocytomas are tumors of the sympathetic nervous system which secrete excessive quantities of the catecholamines, adrenalin and noradrenalin into the blood stream.[8] About 90% originate from the adrenal medulla. Approximately 10% originate within the para-aortic bodies (organs of Zuckerkardl) and are termed paragangliomas.[23]

The first description of pheochromocytoma was made by Frankel in 1886. Paroxysmal symptoms were described by Labbe in 1922. The first successful removal was done by Mayo in 1927. In 1928 Pincoffs made the first preoperative diagnosis.[23]

Incidence

Pheochromocytoma may occur equally in both sexes. The youngest reported patient was a three-month-old baby. The peak incidence is between 20 and 50 years.

Occurrence

Miles reported that pheochromocytoma occurred in 1.3 per 100,000 admissions. Grace Hospital in Detroit, Michigan, reported an occurrence of 2.5 per 100,000 admissions.[32] Among hypertensives: Smithwick, 5 per 1,000 during sympathectomy; Graham, 5 per 1,000 during sympathectomy; Kvale, 6 per 1,000 hypertensive studies. Body Build: Almost always thin.[8]

Pathology

Ten per cent of the tumors are bilateral; if unilateral, the tumor usually occurs on the right side. Pheochromocytoma may be familial. Tisherman et al. described the occurrence of pheochromocytomas in several branches of a large family, frequent neurocutaneous disorders in other members, and an association of the tumors with metabolic cataracts and renal artery stenosis.[25] Calkins and Howard described the first familial occurrence of

---

*Medical Grand Rounds, Mt. Sinai Hospital, October 13, 1964.

Continued

pheochromocytoma in 1947. Since then, 12 other affected kindreds have been identified for a total of 13 cases. About 20% of these tumors are multiple.

The tumors usually range from 1 to 10 centimeters in size, but several weighing up to 2,000 grams have been reported. They are usually encapsulated and are soft to firm in consistency, depending upon their size and the extent of degenerative change. The external surfaces are gray, whitish-yellow, or most often reddish-brown in color. All are well vascularized. They may metastasize to liver and bones, but histologically it is quite difficult to predict malignancy in the primary tumor.

Sites

90% in adrenal medulla; 10% — extra adrenal; a) Organ of Zuckerkardl — reported by Ortega in 1952. b) Pleural cavity — Philips, 1940. c) Hilum of the kidney — Von Euler et al., 1955. d) Urinary bladder — Zimmerman, 1953, — 13 cases reported.[30]

Clinical Types

There are many clinical types, but the simplest division is into two categories.

Persistent Hypertension

This group of patients have persistent rather than intermittent hypertension. In the Mayo Clinic series, two out of three were women. In this type paroxysmal attacks are common and blood pressure goes to much higher levels. Blood sugars were elevated in two thirds of the Mayo Clinic series and the basal metabolism rate was high in 90%.

Paroxysmal Hypertension

Peak age is from 30 to 50 years, with equal frequency in males and females. Attacks or spells may occur as often as every hour or as seldom as once in two or three months. They may last only 30 seconds or as long as one week. Headache is the most common symptom. Palpitation, perspiration, pallor, nervousness and tremor occur less often.

Symptomatology

The symptoms and findings during spells or attacks are variable. Hypertension (persistent or paroxysmal), headache, palpitation, perspiration, pallor, nervousness, tremor, vasomotor phenomena, elevated body temperature, gastrointestinal symptoms, weight loss, glucose intolerance, glycosuria and increased basal metabolism rate, all may occur or only a few may be present.

Diagnosis

The diagnosis of pheochromocytoma cannot be established on the basis of symptomatology alone, since many conditions such as cerebrovascular insufficiency, hyperventilation syndrome, paroxysmal tachycardia, migraine headache, hyperthyroidism, and anxiety states may be responsible for similar symptomatology.

Suspicious Symptoms

Pheochromocytoma should be looked for if one finds: 1. hypertension, paroxysmal or persistent; 2. hyperglycemia and glycosuria without ketosis; 3. hypermetabolism — tachycardia, excessive sweating, etc.; 4. recurrent bizarre spells.

One must correlate the above symptomatology with positive pharmacologic tests (Regitine, Histamine, Tyramine) and demonstration of elevated levels of metabolites or norepinephrine and epinephrine, such as vanillan mandelic acid and plasma and urinary catecholamines.

Suprarenal Mass

Further evidence for pheochromocytoma is the demonstration of a suprarenal mass by: 1. plain X-ray film, 2. excretory urogram, 3. excretory urogram tomography, 4. cystoscopic examination, 5. abdominal aortography, 6. presacral injection of CO_2.

Summary

The diagnosis of pheochromocytoma should be based on cumulative evidence from four features of the disease: 1. witnessing of a typical spell with documentation of associated hypertension; 2. presence of elevated values of catecholamines in the urine or plasma, or a positive vanillan mandelic acid (VMA) test, preferably after a hypertensive episode; 3. positive response to pharmacologic testing: "provocative" Histamine test in normotensives or "suppressive" Regitine test in hypertensives or during the hypertensive crisis, or a positive Tyramine provocative test; and 4. presence of metabolic effects of epinephrine; positive glucose tolerance test, hypermetabolism without hyperthyroidism.[11]

Electrocardiographic Changes

There are several electrocardiographic abnormalities which are found in pheochromocytoma:[35]

Abnormalities of rhythm, such as: 1. wandering pacemaker, 2. auricular tachycardia, 3. sinoauricular dissociation, 4. auricular premature contractions, 5. auricular flutter, 6. auricular fibrillation, 7. nodal tachycardia, 8. ventricular premature contraction, and 9. ventricular tachycardia.

Abnormalities of ischemia include: 1. low amplitude or inverted T-wave, 2. prominent P waves, and 3. characteristic diffuse distribution of T and ST wave changes.

Localization of Tumor

Once the diagnosis is established, an attempt should be made to localize the tumor by: 1. Palpation of abdominal quadrants. About 14% of cases are palpable.[6] 2. Intravenous pyelograms may show the tumor distorting the renal pelvis or displacing the kidney in 56% of unselected adult cases[6] and 31% of the cases in children.[5] 3. The tumor can sometimes be located by tomography, calcification being seen on the X-ray film or by the production of a hypertensive attack by massage in a particular body area.[5] 4. Presacral air injections and aortography are helpful but carry some risk. 5. When localization is particularly essential (e.g., following negative surgical abdominal exploration), a catheter may be inserted into the vena

Continued

cava and samples of blood obtained at different levels for catecholamine determination.[7]

Treatment

The treatment of choice is surgical removal of all tumor tissue. However, if the patient is a very poor surgical risk, drug therapy may be tried. Bellas treated a patient for eight years with Phentolamine Hydrochloride, 25 mg. every three hours during the waking hours.[20] Alpha Methyldopa, a decarboxylase inhibitor, will decrease norepinephrine production.[24] It may also be used to diminish sweating, flushes, palpitations and headache in unresectable pheochromocytoma.[29]

The efficacy of the prolonged administration of oral Phentolamine was first demonstrated by Iseri et al. and has been recently recommended as preoperative treatment for all patients with pheochromocytoma.[36]

Diagnostic Tests

Many drug tests have been suggested to differentiate between essential hypertension and pheochromocytoma. However, none are completely reliable. The tests also carry some danger, and fatal results have been reported. The following tests have been used.

Histamine Test

The first pharmacologic test was the Histamine test introduced by Roth and Kvale in 1945. This test is used when the basal blood pressure is less than 170/110. Five hundredths of a milligram of Histamine base in 0.5 ml. of normal saline solution is injected intravenously, after basal blood pressure is established. As a precautionary measure, Regitine should be ready for immediate administration if the blood pressure becomes alarmingly high. A cold pressor test should be done just prior to the Histamine test.

Blood pressure is determined every 30 seconds after the injection. Usually the blood pressure increases rapidly and is maximal in two minutes. The test is positive if the systolic pressure rises 20 mm. of Hg or more above the highest reading obtained with the cold-pressure test. This rise in blood pressure, usually accompanied by symptoms which characterize an attack, should occur within two minutes after the injection of Histamine, following an initial drop in blood pressure which occurs in the first 30 seconds after injecting Histamine. If the test is positive, one should inject 5 mg. of Regitine intravenously to abort the attack induced by the Histamine. This is also additional diagnostic evidence, if abortion of the attack occurs.

Phentolamine Test

If basal blood pressure is above 170/110, 5 mg. of Phentolamine (Regitine) is given intravenously. If blood pressure drops by at least 35 mm. of Hg in the first four or five minutes after injection and then returns to the basal level in 10 to 15 minutes, the test is positive. A decrease in the blood pressure in some apprehensive patients may occur during the first one to two minutes in the absence of a tumor; but the blood pressure returns to the basal level in one to two minutes.

Mecholyl Test

Mecholyl, like Histamine, stimulates the release of catecholamines from the tumor. The dose is 10 to 25 mg. subcutaneously. But it offers no advantage over the Histamine test and is more dangerous.

Dibenamine Test

Four hundred mg. in 500 ml. of 5% dextrose is injected intravenously over one to two-hour periods, producing a slowly developing but prolonged lowering of blood pressure. However, the test is neither specific nor reliable.[3]

Tetraethylammonium Test

This drug causes a release of catecholamines from the tumor and also blocks regulating mechanisms of secretion. It is seldom used.[4]

Benzo Dioxane Test

Fifteen to 20 mg. is given intravenously over a period of two to three minutes, during which the blood pressure is recorded at 30-second intervals for three minutes and then 60-second intervals for 15 minutes. A fall of 30 mm. within four minutes after the start of injection is a positive test. Dangerous pressor responses sometimes occur with or without a pheochromocytoma. False negative reactions are more common than with Regitine.[2]

Tyramine Test

Recently a new test has been reported: the tyramine test. An intravenous infusion of 5% dextrose is started in one arm, and blood pressures are determined in the other arm using a mercury manometer and inflatable cuff. Basal blood pressure is then established within 10 to 20 minutes. Before doses of Tyramine (500 μg to 2,000 μg) are given, it must be established that there is no response to the injection of a placebo(isotonic sodium chloride solution). The blood pressure is recorded every 30 seconds after injection until the systolic blood pressure returns to the base line. The blood pressure is again recorded for another 10 to 15 minutes, after which another injection is given. A positive test is a rise in systolic pressure of 40 mm. or more within two minutes and a return to base line within 12 minutes after injection. This test has few reactions; no disturbing symptoms are elicited; and it is easy to perform.[12]

Pitfalls Encountered in Various Diagnostic Tests

It is essential in the use of the pharmacological tests that a reliable basal blood pressure be obtained. This is often neglected.

False positive results may occur if sedatives or narcotics are taken within 48 hours of the test. Sedatives inhibit the blood-pressure rise during the cold pressor test, and increase in the blood pressure during the Histamine test may be greater than during the cold pressure test, suggesting the presence of a tumor. Sedatives and tranquilizers in patients with sustained hypertension may cause a fall in blood pressure typical of that produced in pheochromocytoma following intravenous Regitine. Uremia may cause a false positive Regitine test. Antihypertensive drugs should be withheld during the same period.

Hydralazine hydrochloride (Apresoline) and Reserpine should not be given for at least two weeks prior to testing, as these drugs produce false

Continued

negative results. Vasoconstrictive drugs used for nasal stuffiness may produce a profound fall in blood pressure for as long as 40 minutes after intravenous Regitine.

The disadvantages of catecholamines are: 1. they require services of skilled technicians and equipment of a type found in only the more elaborate research laboratories. 2. Meticulous attention must be paid to the patient's previous medicines. 3. Technique of preservation of urine samples is necessary. 4. Timing of collection of samples in those patients whose symptoms are paroxysmal in nature is required.[8]

Vanillan mandelic acid (VMA) is increased in shock, coma, metastatic malignancies, pulmonary insufficiency, or carcinoid tumor with metastasis.[21]

Increased catecholamines may be found 1. in patients who have received adrenergic products like Reserpine, Vitamin B_{12}, or barbiturates; 2. in patients who have eaten bananas or vanilla, and 3. in patients with anxiety or after strenuous physical exercise.[8]

Increased urinary vanillan mandelic acid (VMA) is found in patients with neuroblastomas, ganglioneuromas and ganglioneuroblastoma.[8]

Case Report

A 26-year-old married white woman was admitted to Mount Sinai Hospital, September 13, 1964, with chief complaints of headache and high blood pressure. She had had recurrent severe headaches for three years but no apparent hypertension. Three months before admission, elevated blood pressure (180/120) was discovered during a routine examination. Hypertension persisted during this three-month period. She denied any paroxysmal "spells," however, though her headaches were intermittent, coming on suddenly and lasting one to four hours. She had always been underweight and thin. Prior to admission she had been admitted to another hospital where a Regitine test was positive and an intravenous urogram and an aortogram revealed findings suggesting depression of the left kidney by a suprarenal mass. Urinary catecholamines were 29 mcg/24 hr. (normal: up to 103 mcg/24 hr.). She was admitted to Mount Sinai Hospital for surgical exploration.

Physical Examination

An examination on admission revealed a thin young woman complaining of headache. Blood pressure was 180 systolic and 124 diastolic in both arms. Peripheral arterial pulses, including femorals, were normal. The retinae showed arteriolar narrowing and A-V nicking. The aortic second heart sound was accentuated. No abdominal masses were felt. The remainder of the physical and neurological examination was negative.

Laboratory Studies

Hemoglobin, white blood count, sedimentation rate and urinalysis were normal. BUN was 19 mg%, CO_2 content 26 meq/1, chlorides 103 meq/1, sodium 141 meq/1, and potassium 4.6 meq/1. Prothrombin time was normal. Fasting blood sugar was 90 mg%. PSP dye excretion was normal. Urine culture was negative. Urinary 24-hour sodium and potassium were 154 and 90 meq, respectively. Urinary catecholamine excretion was 358 mcg/24 hr. (Normal: up to 103 mcg/24 hr.) Chest X ray showed minimal left ventricular enlargement. An electrocardiogram showed S-T-T wave changes consistent with left ventricular hypertrophy.

Hospital Course

The patient's blood pressure fluctuated in the range of 140/84 to 210/130 following admission. A Regitine test was done beginning with a basal pressure of 184/118. Within one minute after intravenous injection of 5 mg. Regitine, the blood pressure fell to 138/80 and then gradually rose over 10 minutes to 164/110.

On September 18, 1964, an abdominal exploratory operation was performed. The kidneys appeared normal and no adrenal mass was present. The upper and lower abdomen was explored by palpation and no abnormality found. A renal biopsy was taken and the abdomen closed. Histologic examination of the removed renal tissue revealed moderate arteriolar nephrosclerosis.

The patient made an uneventful recovery from surgery and was discharged from the hospital to be managed as an outpatient with antihypertensive drug therapy.

No Words Wasted

Babbling women were the bane of Abernethy's* life. He would interrupt them by ordering them to open their mouths, then tell them 'Now shut your mouth and keep it shut.' One tale is of a lady who called on him with a cut finger. The dialogue went:

First day: Abernethy: Cut?
Patient: Bite.
Abernethy: Dog?
Patient: Parrot.
Abernethy: Go home and poultice it.
Second day: Abernethy: Better?
Patient: Worse.
Abernethy: Go home and poultice it again.
Third day: Abernethy: Better?
Patient: Well.
Abernethy: You are the most sensible woman I ever met. Good-bye. Get out.**

Problems in Estimating Disability**

ROBERT H. KENNEDY, M.D., F.A.C.S.
New York, New York

Are Workmen's Compensation Laws Outmoded?

DETERMINING PERCENTAGE of disability is a complicated subject. The items to be considered are so numerous and the problems so varied that they should be fed into an IBM machine for computation rather than added to the burden of busy practicing physicians. By definition,* permanent impairment "is a purely medical condition, which is a contributing factor to, but not necessarily an indication of, the extent of a patient's permanent disability. The social and economic effects of permanent impairment must be evaluated by administrators in making determinations of permanent disability."[1] Throughout my surgical career I have declined to estimate percentage disability for any patient's attorney or any insurance company. There are several reasons for this, but one of the most practical is that the figures merely furnish an opportunity for argument among attorneys, claims agents and doctors, whose figures often vary between 10% and 90% disability in the same case. As Kessler, an outstanding specialist in rehabilitation, has said: "No doctor or individual *can* evaluate disability. No man in the world can tell you how much a man is worth, how much work he can do."

Somers and Somers[2] say: "There are two general types of permanent partial disability: (1) those involving the loss or loss-of-use of a readily identifiable member of the body, commonly called 'scheduled' disabilities, and (2) those which cannot be so classified, known as 'non-scheduled' disabilities. Injuries to the back, head, and nervous system are frequent examples of the latter." (However, in Minnesota in 1947 the result of back

Continued

injuries was made a scheduled disability.) "Compensation involves the difficult problem of determining the degree of incapacity resulting from the injury. Not surprisingly, permanent-partial cases are the cause of a disproportionate share of the administrative tribulations of compensation officials and also represent an inordinately high proportion of benefits."

Schedule awards are completely unscientific. "For example,[3] the loss of an arm in Minnesota is worth 270 weeks, in New York 312 weeks, in Maine 150 weeks, in Vermont 170 weeks, in South Dakota and Texas 200 weeks. Schedule awards merely represent legislative estimates of the proportion that the loss or loss-of-use of a member bears to total disability." "Would[4] you write a mechanical rule categorically stating that loss of hearing is more harmful for all workers than loss of a foot, or vice versa? Workmen's Compensation laws do this, regardless of the occupation, age, and training of the injured worker. In six states, loss of a foot is rated equal to the loss of hearing in both ears; in eleven states, the loss of a foot is rated higher; in 28 states (including Minnesota) deafness is considered more injurious."

The Influence of Liability

In estimating a disability the physician should use the same factors, regardless of the cause of the accident or place of work.

From the economic or insurance viewpoint the following four types of injured individuals must be considered:

1. The injured person who assumes his own financial responsibility: i.e., has no insurance. This person usually recovers most quickly and completely.

2. The injured person who carries accident insurance in some form, e.g., a group policy paid for by his employer, his own accident policy, or Blue Cross and Blue Shield paid for personally or by his employer. Such coverage is held by probably 70% of our population.

3. The employee injured while at work who is covered by compensation insurance. Not more than 20% of accidents will be compensation cases.

4. An individual who is injured off the job under conditions where there may be liability under the common law, or a member of the Armed Forces eligible for Veterans Administration Hospital care, or an individual working for public welfare departments.

Many injured persons are covered by several types of insurance and may be able to use more than one for any given problem.

Evidence of Physical Ability and Employability

A broken leg in a sedentary worker might make little difference in carrying on his job, whereas a longshoreman might need to change his occupation. Facial scars might mean nonacceptability for return as a public relations man or a salesman. McBride[5] says that subjective symptoms, unsupported by clinical evidence of their recent development, should be discounted.

After his condition has been assessed through history, examination, laboratory investigation, and X rays, consideration is given as to how his potential has been altered as a result of the accident.

The extent to which a person will be limited in his work after an accident will depend on his attitude as well as his physical condition. The economic opportunities available will also affect his recovery. He will readjust according to his education and skills. His mental and moral reactions to being dependent on the community, and his willingness to try, all have to be considered. The older person is less able to adjust. Following an accident with permanent partial disability, consideration needs to be given to the safety of the workman himself on his old job, as well as to the safety of others where he is working.

If legislatures or commissions wish to pass laws or regulations regarding rating, they should be responsible for establishing percentages of total disability based on the findings of medical examinations. The compensation laws in most states disregard occupational variations. Loss of earning capacity in ordinary manual labor is recognized; therefore the administrative personnel ought to have authority to adjust the schedule within limits, taking into account various factors about the individual concerned.

Lump-Sum Settlements

There is still too great a tendency to try to buy off the claimant. A lump-sum settlement appeals to the person who has been unable to work for a while, and who with his family is living theoretically on two thirds of his usual income. This figure is an error, since it has been shown repeatedly that the payment is only about half that amount, i.e., one third of his regular income. With few exceptions, "today's injured workers suffer a much greater loss than the early lawmakers contemplated."[6] "The granting of lump-sum payments is an easy, but a deplorable, way of 'closing' a compensation case. It too frequently operates for dissipation of funds and throws the injured employee upon charity in order that he may obtain subsistence. Worst of all is the physical and moral effect of failure on the part of the injured employee to obtain rehabilitation."[7] The settlement is usually for less than the claimant would receive through periodic payments. In Illinois it is estimated that 80-85% of all cash benefits are lump-sum settlements. To the employer and the carrier this is almost always a financial gain. Instead of allowing steady increase in the number of lump-sum settlements, an effort should be made to increase maximum weekly compensation payments. Otherwise this situation could lead to the abolition of private insurance, as happened in England.

Lump-sum settlements offer a multifarious* problem. For example, they lead to false estimates of disability. Theoretically, an estimate should not be made until maximum improvement has been reached, which commonly presupposes providing rehabilitation. To quote from Lane:[3] "It is said that the injured workman must choose between maximizing his injury to increase monetary compensation and minimizing his injury through rehabilitation . . . at the expense of diminishing or terminating his compensation . . . This affords one reason why so few injured workmen seek the benefits of rehabilitation . . . Historically . . . workmen's compensation was a statutory device which its advocates hoped would afford injured workmen a speedy, inexpensive, non-litigious method of securing compensation for industrially caused injuries in place of the common law employers' liability system with its defenses largely weighted in favor of the employer." For those few employees able to establish liability, the judgments were substantial. Regardless of whether we are working under a legal or medical hearing system, rehabilitation should be started on the day the injury occurs.

Monetary Benefits

A factor to be taken into consideration in estimating disability is undoubtedly the common knowledge that the benefits are inadequate, that a workman must frequently borrow money following an occupational injury in order that he and his family may eat. Statutory benefits have not kept pace with the rising cost of living and there has been little sustained effort to increase compensation. These benefits are often even below relief allowances. A variety of programs, both public and private, however, are supplementing or substituting for workmen's compensation. Good labor relations have brought about many of the reforms that compensation was expected to influence. Employees are now safer on the job than off it. Increasingly the whole Social Security program has made the economic function of compensation incongruous.

Supplementary Benefits When Disabled

Some of the programs to "indemnify or offer income maintenance to injured workers and their dependents are:

"1. Private programs compensating for occupational disability or death, financed by employers alone or jointly by employers and workers; . . .

"3. Employers' liability for injured workers in states which permit employers to elect not to be covered by workmen's compensation; (This is not true in Minnesota.)

"4. The common law . . . for domestics,

Continued

---

*See Test Your Word Score Page 211.

farmers, and others where excluded from both workmen's compensation and employers' liability;

"5. Federal death and survivorship benefits through OASI and the Railroad Retirement system; . . .

"8. Federal-State public assistance programs, especially Aid to the Totally and Permanently Disabled, Aid to the Blind, and Aid to Dependent Children."[2]

If health insurance, voluntary or compulsory, is adopted, many of the medical needs under workmen's compensation will be covered. Group life, retirement, accident, and health insurance may have a profound effect on the future of workmen's compensation. The unions have been negotiating contracts which cover nonoccupational disability programs with more generous benefits than from workmen's compensation. From overlapping benefits it is often possible in death cases to obtain family payments larger than the deceased's normal earnings. These programs have taken the pressure off workmen's compensation, so that little attempt need be made to improve its inadequacies. Employers without compensation coverage are now seeking to obtain this in order to escape the higher costs of personal injury suits. Efforts are being made to give the injured employee covered under compensation the right to sue where injury was due to negligence of the employer. Some even go as far as suggesting that the employee be allowed to keep both awards.

Conclusions

As laws and directives in workmen's compensation have multiplied, more factors have to be decided by administrators than by doctors. The percentages of disability which many doctors determine are of questionable value. Remuneration under workmen's compensation laws is playing a progressively diminishing part in the economics of the workingman. After 50 years of experience have workmen's compensation laws outlived their usefulness?

Abstracts, Briefs and Commentaries

A VIEW OF MEDICINE IN BRITAIN

The Pharos, the official publication of A.O.A., the Honorary Medical Society, has an article of unusual interest by Ernest Craige, M.D. Dr. Craige is a professor of medicine at the University of North Carolina Medical School.

During the year 1963-64, Dr. Craige held a Commonwealth Fund grant to carry out research in congenital heart disease at St. George's Hospital in London. This article reviews in a masterful manner his observations on the aspects of the National Health Service in Great Britain, at present undergoing a critical review, owing largely to the growing discontent among general practitioners. The present wave of indignation is in part due to the promised hike in pay which fell well below that anticipated. However, mounting protests in the British Medical Journal and in the lay press indicate a deeper discontent than remuneration alone. Conditions of practice and apprehension over the whole future of the profession are fundamental. Under the plans of organization of the National Health Service, general practitioners insisted they should remain independent professional men rather than salaried employees. They are paid an annual total based on the number of patients on their lists (maximum 350), with a few ways of supplementing earnings. The general practitioner fees are derived from a central pool which averages out at about 2742 pounds (less than $7000), plus an estimated amount for expenses of practice. A minor amount taken from the pool for extra service before division into shares penalizes the group and creates unhappiness.

Any payments for office renovations, secretarial or laboratory ancillary help must come out of gross pay. The estimated cost of practice expense based on a national average may be inadequate, and there is no provision for capital improvements. One partnership recently improved their surgery (office) at an expense of 2000 pounds. They received no reimbursement for the outlay, and were shocked to find their taxes had gone up because of the improvements.

Many general practitioners have no hospital privileges, which widens the gulf between them and those who have. They complain that their duties

Continued

consist more of filling out certificates for inability to work, free appliances, and sorting out from the mass of patients those who are really sick and who are sent to the hospital for consultant's care. General practitioners are discouraged by the large number of office patients to be seen and the cost of extra studies which comes from their gross income. Since income per service rendered constitutes on the average only six shillings (84¢), there is little inclination to provide elaborate technical studies. In spite of these conditions, however, many general practitioners perform admirable service.

"Letters to the British Medical Journal speak of the disillusionment of general practice, a blind alley occupation, or a dead end." In spite of this, however, the severe critics seem to have no desire to return to the preexisting system. Consultation and elaborate studies by consultants cost the patient nothing regardless of his ability to pay.

As a medical student nears graduation he chooses between general practice and consultant practice. In either case he applies for a position of house physician (intern) in as good a hospital as possible. Following a year or two of training the trainee becoming a general practitioner may seek a post as assistant to a practitioner and later obtain an appointment as a principal in the National Health Service with his own practice. If he elects to stay in hospital training with a goal of consultant, he must take a succession of jobs in general medicine and surgery and finally enter a more specialized field. After seven to 12 years he may acquire the status of consultant. "This, however, can only occur when an existing post becomes vacant upon the death or retirement of the incumbent." In view of the fact that there are many persons seeking this appointment, he finds he has completed a prolonged training program that is over-subscribed with an endless period of frustration and waiting. A consultant may have assistants (registrars) who have had years of preparation, who became teachers or researchers, and who have a private practice. The author observed some registrars with five to nine years following graduation without promotion. Some emigrate rather than wait longer for promotion. Like the general practitioner, they dare not complain, as their promotion to consultant depends on the goodwill of those in authority.

Hospital construction has been neglected and almost half of the hospitals in Britain are over 70 years old.

In summary, the author states that there are, nevertheless, some good achievements. After 16 years, the National Health Service has not devised a system that satisfies the general practitioner intellectually or financially, as evidenced by falling recruitment plus the migration of frustrated young graduates. But he suspects that as the older general practitioners— "products of an earlier mold" drop out, they will be replaced by new younger ones, who having known nothing different will be more contented civil servants. "Therefore, it seems to me more likely that the general practitioner will suffer an invertebrate evolution rather than the National Health Service a revolution."

"From this rather gloomy view, one needn't derive a sense of complacency with regard to the American scene." He believes there is strength in the diversity of our methods. General practitioners have freedom. Some of his British friends blame the inadequacies of their system not on the government planners but on the ineptitude and lack of vision on the part of the professional negotiators.

Discussion

In the May issue of Minnesota Medicine I reviewed an article published in the Lancet— "Status of Medical Practice in England." This review, although similar, is such a fine presentation written by one of our outstanding teachers, based on one-year observations, and seems unusually timely. There are several quotes which I consider worthy of serious consideration by our medical profession. The inroads of socialization in government and medicine are obvious. Let our profession and its governing bodies not be accused of ineptitude and lack of vision.

In hopes that I may not be considered overly critical in these reviews, may I state that during my two years in service with the British, I developed a deep respect for them, their sincerity, and their loyalty, but less for their system of medicine.

Stanley R. Maxeiner, M.D.
Minneapolis, Minnesota

IRRADIATION TREATMENT FOR PEPTIC ULCER

X-ray irradiation of the stomach in the treatment of peptic ulcer was first suggested in 1909, and by 1935 over 200 papers had been published on this treatment. Careful studies on thousands of patients have established that irradiation reduced the recurrence rate to one fifth and hastened healing. Nevertheless, this use of irradiation is not generally known and has not been widely adopted. Many prefer surgery despite its risks and the dumping syndrome it often produces..

The technique of irradiation is simple: the stomach is outlined with barium and the skin marked during fluoroscopy. An anterior and posterior field is centered over the upper two thirds of the stomach (where the acid-secreting cells are). An irradiation dose of 2000 r. is given through each port in six to eight treatments. In most institutions the 250-kv. apparatus is used.

Results are reported in 121 patients with complicated peptic ulcer, 79 of whom have been followed up for over four years, after cobalt 60 teletherapy. The reactions were minimal.

A total of 629 gastric secretion studies were done. In 90 percent of the patients the basal gastric secretion was reduced more than 50 percent in the first six months, though hyperacidity usually recurred after six months to one year. In 87 cases the ulcer did not recur; in 13 there was a questionable recurrence and in 21 a definite recurrence.

Cobalt 60 teletherapy is a very useful method of treating peptic ulcer, especially in cases where cardiac lesions, hypertension or other complications contraindicate surgery.

SYMPATHECTOMY FOR FROSTBITE

A well controlled laboratory study has been conducted by the authors to evaluate the effect of sympathectomy in the frozen hind leg of rabbits. In addition to the controlled group with no sympathectomy, three other groups were studied, one with a sympathectomy three days prior to freezing injury; another within one hour after freezing and thawing; and finally another group 24 hours thereafter. A definite improvement in tissue survival followed sympathectomy when accomplished as quickly as possible after the freezing and thawing procedure.

The authors point out that immediately after thawing there is a transient vascular spasm followed within a few minutes by resumption of blood flow, then by an appearance of hyperemia with decreased and finally absent flow within the capillaries. This was followed ultimately by a thrombosis if the spasm is unconnected. A venous spasm lasts up to 24 hours, but arteriolar spasm remains beyond that point. They also point out that rapid thawing of the frozen tissue improves the degree of tissue survival, and suggest an optimal temperature of 42 to 43 degrees centigrade.

No clinical human studies have been done by these authors on this particular procedure. However, it would seem well established that timing of the sympathectomy is very significant.

COMMUNITY-WIDE EXPERIENCE WITH LIVE VIRUS MEASLES VACCINE

The two physicians of Cook County, Minnesota, enlisted the help of local citizens to provide a measles immunization program for the 1416 school children in this isolated community. As reported by R. A. MacDonald, M.D., of Grand Marais, efforts to promote measles immunization on a private patient basis were slowed by professional reluctance to "advertise" the vaccine and relatively high cost on a per unit basis. Working with local health organizations, two lay groups ultimately underwrote the cost of the project and volunteer workers assisted professional nurses in arranging clinics, and making follow-up visits to all vaccinated children.

For $3.00 each child received live virus vaccine at a dose 0.01 ml. per pound plus gamma globulin. Infants less than 11 months of age were excluded in order to avoid abortive immunizations. Of 1349 children from one to 18 years old, 564 gave a history of rubeola, and were thus considered immune. Of those nonimmune, 454 received the vaccine, and thus 74% of the school population were then considered immune. There were 10 reactions, mainly mild rubeola; convulsions occurred four hours after injection of an eight-year-old boy found to have an unsuspected acute tonsillitis. There were no allergic reactions.

This report demonstrates again the remarkable results achievable when physicians and laymen work together toward a common goal.

SPRAINED ANKLE

Of a total of 103 acutely injured ankles seen by the author during a six-month period, 85 presented simple sprain, and 18 were fractured. This proportion does not represent the true incidence of ankle fracture, for a number of patients were referred directly to a fracture clinic. To diagnose the extent and seriousness of the injury, a brief medical history was taken and the ankle was first examined clinically. A careful note was made of the exact site of swelling and of tenderness, in relation to the ligamentous attachments and the bony points. The ankle was exposed to a full range of passive movements, and any limitation, or any increase, in range was evaluated by comparison with the patient's normal ankle. Only if the affected ankle showed a greater range of inversion than the normal, or if there was tenderness over the attachments of the calcaneofibular ligaments, were X ray pictures of the anteroposterior and lateral views taken. The patients were treated at random with adhesive strapping (30 patients) and by injection of hyaluronidase into the injured ligament (38). In three quarters of the hyaluronidase-treated group the therapy resulted in pain-free walking in less than half the time taken for a similar proportion of patients treated with adhesive strapping to achieve similar results. The severity of the injury, the patient's age, and the interval between the trauma and the treatment may have influenced the results. A follow-up two years after the treatment indicated that the short-term advantages were not outweighed by any long-term disadvantages. In none of the patients available for the follow-up did failure to immobilize a sprained ankle result in any serious long-term disability.

VAGINAL METASTASES FOLLOWING TREATMENT OF ENDOMETRIAL CARCINOMA

These authors report 269 cases of endometrial carcinoma in which they observed a post-treatment vaginal metastases incidence of 4.4%. This low incidence when compared to other published reports is attributed by the authors to preoperative prophylactic radiation therapy to the uterus and upper vagina.

Evaluation of the histologic patterns of the primary lesions showed an apparently higher incidence of vaginal metastases when the carcinoma was poorly differentiated or when deep myometrial or lower uterine segment extension of the lesion was present. Virtually no vaginal recurrences after treatment appeared if the primary lesion was confined to the endometrium or was of an early well-differentiated histologic pattern.

The incidence of vaginal recurrence was nearly identical among patients treated with radium (3.7%) or with radiation and surgery (3.8%). Vaginal metastases subsequently developed in five or 26.3% of 19 patients treated by surgery alone.

Continued

Treatment of the vaginal recurrences was individualized and related to location of the lesion. Most were treated by intravaginal radium and external radiation. Two underwent vaginectomy. The over-all five-year survival rate among those with vaginal metastases was 27.2%.

On the basis of the data presented, the authors plead for prophylactic preoperative radiation in the treatment of endometrial carcinoma to reduce the incidence of subsequent vaginal metastases.

Discussion: Vaginal recurrence subsequent to treatment for adenocarcinoma of the endometrium is certainly not a rare occurrence. It appears at some time or another in about 10% of the patients with this disease. The possibility of vaginal recurrence should always be considered before primary treatment is begun. Appropriate modification of standard therapeutic techniques is indicated to lessen the chance of vaginal recurrence among patients who are predisposed to this complication. Many articles in addition to this one have demonstrated that certain patients are more likely to develop post-treatment vaginal recurrence than others. In addition to the anaplastic lesion or the lesion which deeply invades the myometrium or extends into the lower uterine segment as mentioned in the reviewed article, experience at the University of Minnesota has shown that extension of the primary lesion downward into the cervical canal also carries a very high risk of post-treatment recurrence. The identification of cervical canal extension is not difficult if the patient with suspected endometrial adenocarcinoma is subjected to a differential or fractional curettage of the uterine cervix and corpus for an exact and detailed diagnosis.

Most gynecologists experienced with this problem agree that intensive preoperative radiation is indeed indicated to reduce the incidence of subsequent vaginal metastases and also pelvic recurrence not only in the high-risk patient categories suggested by the authors but also in the patient with endocervical extension. The patient, however, who has a small, mobile uterus and a superficial highly-differentiated lesion need not and should not be routinely subjected to preoperative radiation. The prognosis for complete cure by simple hysterectomy and removal of the adnexa in this type of lesion is excellent and the prospect for subsequent vaginal recurrence is almost nil even without preoperative radium and external radiation therapy.

The high incidence reported in the article of vaginal recurrence among patients treated only with surgery does not reflect the experience at the University of Minnesota where the vaginal recurrence rate after hysterectomy is 8-10 per cent. The number of cases reported by the authors in the abstracted article is too small to be of true value in analyzing the magnitude of the problem and to compare with larger groups of patients treated in a similar manner.

The prognosis for the patient with post-treatment vaginal recurrence is not a hopeless one. Several reports have shown a 25-50 per cent five-year survival rate after appropriate treatment to the lesion has been administered.

WIDE LYMPH NODE DISSECTION FOR CARCINOMA OF LEFT HALF OF COLON

Bacon and Khubchandani have extended the lymph node dissection for left colon carcinoma to the root of the inferior mesenteric artery, and have also included sectioning of the inferior mesenteric artery. They have pointed out that without this extensive lymph node dissection their studies indicate that nine per cent of all the operations by the usual method would have left involvement of lymph nodes. They carry out this procedure for the cure of patients with cancer of the descending colon, the sigmoid, rectum, and anal canal and the only contraindications are in elderly patients, poor-risk patients, and patients with extreme obesity. Though the operation is somewhat prolonged, the morbidity was not particularly greater than that associated with the conventional type of operation.

Depending upon the site of the lesion, the percentage of improvement in the five-year survival was from four to ten per cent. The greatest improvement was observed in patients when the malignancy was located in the descending colon or sigmoid. The authors were able to conclude that there was no danger in lowering the blood supply, and that there was adequate collateral circulation from the superior mesentery to keep the anastomosed tissues viable.

They suggest the hope that in the future it will be possible to detect the involved lymphatic chain preoperatively and perform a selective lymphadenectomy.

The Primitive Medicine Man

The medicine man was especially selected. Usually he was marked out from birth. In Liberia twins are regarded as particularly gifted. Seventh sons, as is well known, are attuned to the whisperings of the infinite. And, of course, the seventh son of a seventh son is doubly dyed. One such, a fiery old fellow, in the Highlands of Scotland, who was a militant atheist, was nevertheless up to a few years ago constantly besieged by his neighbors and even awakened in the dead of night to touch sick people brought to his door. ...nothing, that is, except the

sedative-antispasmodic action of DONNATAL®

Functional disturbances of gastrointestinal tone and motility present the physician with an all too common reaction to the stressful dilemmas and frustrations of modern living.[3,6]

For their dependable control, no better spasmolytic has ever been discovered than the *natural* belladonna alkaloids in combination with phenobarbital, as in DONNATAL.

Phenobarbital, as a mild sedative, has the benefit of long use and a reassuring record of freedom from unexpected and untoward reactions. In allaying subjective tension, it helps to prevent emotional stimuli from provoking or intensifying visceral spasm.

The *natural* belladonna alkaloids in DONNATAL—conforming to the classic formulation by Vollmer[5]—selectively include only the therapeutically desired alkaloids in precisely and optimally balanced ratio. The clinical uncertainties of the variable tincture and extract of belladonna are thus avoided.

Further, a recent pharmacological study has confirmed that the antispasmodic effectiveness of the belladonna alkaloids in DONNATAL is measurably potentiated by the presence of phenobarbital.[8]

Over the years, the professional consensus has reflected broad clinical confidence in the marked benefits to be achieved by DONNATAL in a wide range of visceral disorders... in peptic ulcer,[1,6] functional bowel distress,[1] gastrointestinal spasm and discomfort,[2] and other functional disturbances of visceral smooth muscle.

CONTRAINDICATIONS: Glaucoma, advanced renal or hepatic disease or hypersensitivity to any of the ingredients.

PRECAUTIONS: Administer with caution to patients with incipient glaucoma or urinary bladder neck obstruction as in prostatic hypertrophy.

SIDE EFFECTS: Blurring of vision, dry mouth, difficult urination or flushing and dryness of the skin may occur at higher dosage levels, rarely at the usual dose.

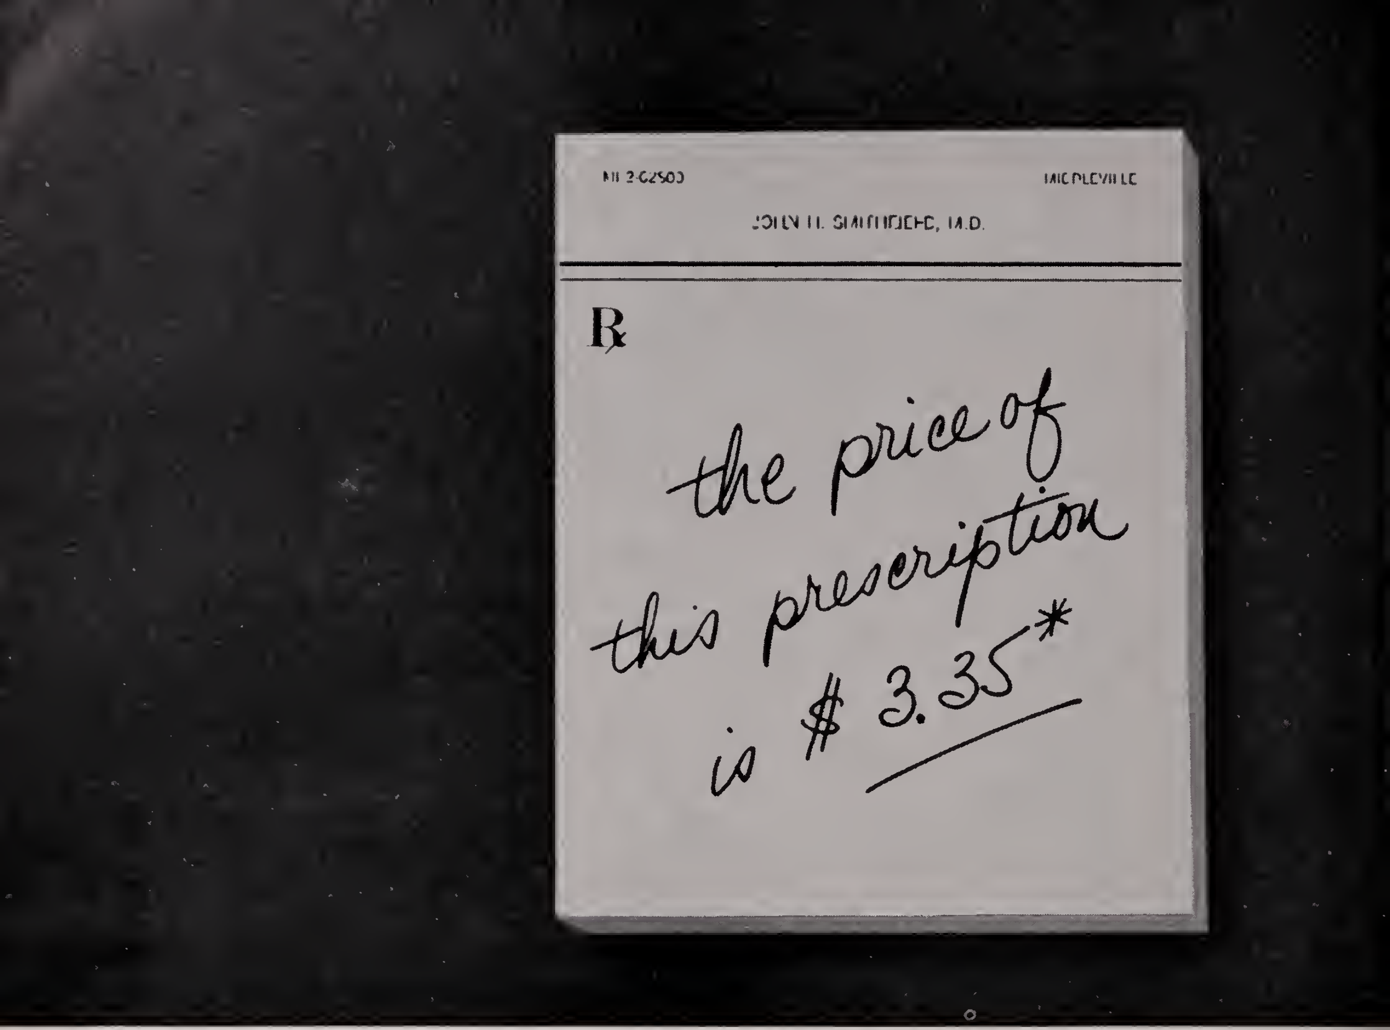
(Warning: May be habit forming.)



How much would it be with no manufacturer's profit?

$2.09? $.93? $3.18?

Somewhat amazingly, $3.18 is correct. Even if you eliminated pharmaceutical manufacturer's net profit, your patient would pay only about 17 cents less for the average prescription—hardly a deciding factor in having it filled. Of course, this assumes that pharmaceuticals could continue to be available without profit (where do new miracle drugs come from, if not profit?).

American pharmaceuticals today may well be America's biggest bargain.

Book Reviews

My books kept me from the ring, the dog-pit, the tavern, and the saloon. — The associate of Pope and Addison, the mind accustomed to the noble though silent discourse of Shakespeare and Milton, will hardly seek or put up with low or evil company and slaves. — Thomas Hood

AN ATLAS OF VASCULAR RINGS AND RELATED MALFORMATIONS OF THE AORTIC ARCH SYSTEM — **James R. Stewart, Owings W. Kinkaid and Jesse E. Edwards. Springfield, Ill., Charles C. Thomas, 1964. 155 pages, index, 216 illus., references.**

Embryology, roentgenology and pathology are welded to form an atlas and classification system of disorders pertinent to the study of peripheral vascular disease. The authors are from the Departments of Roentgenology and Pathology of the University of Minnesota. Dr. Edwards is the author of An Atlas of Acquired Diseases of the Heart and Great Vessels.

A hypothetical model in which none of the developmental regressions of the aortic arch system have taken place is used as a reference point. Division then follows — dependent on position of the aortic arch and the presence of ducti arteriosi. Each condition is illustrated with a drawing of the embryologic origin of the vasculature, photographs of the pathologic specimen and skiagrams when available. There are brief clinical notes.

The atlas succeeds in presenting to clinicians and to others concerned with developmental biology a highly technical and informative study of anomalies of the aortic arch system. Organization is that of the classification system, and makes for easy reference and ready understanding of the morphology. Illustrations are adequate and well reproduced; an extensive bibliography is provided.

George E. Kitzmiller, M.D.
Hennepin County General Hospital
Minneapolis, Minn.

"SIGNS AND SYMPTOMS" — **Cyril Mitchell MacBryde, J. B. Litman Co., 1964. 971 pages.**

This is Fourth Edition of MacBryde's "Signs and Symptoms."

The word symptom is used to name a manifestation of disease, which is usually a subjective observation from the patient.

Pain being a significant sign, the book contains eight chapters dealing with pain, originating from the various sections of the body. By using the table of contents, the reader is able to guide himself into the proper chapter, which may be of interest to him at the moment.

Generalized vasospasm, tachycardia, cough, hemoptysis, dyspnea and cyanosis, direct the reader to a series of chapters devoted principally to cardiovascular and respiratory disease, and then there are a series of signs which direct one to the diseases of the gastrointestinal and biliary system.

Bibliographical references are tendered at the end of each chapter and these, though not extensive, seem to be adequate for more specific reference to the contents within each chapter.

I have found this to be an excellent edition, as a reference for a large variety of signs and symptoms that one encounters from day to day.

Carl O. Rice, M.D.
Minneapolis, Minnesota

OCULAR AND ADNEXAL TUMORS — **New and Controversial Aspects, Edited by Milton Boniuk, M.D., C. V. Mosby Co., St. Louis, 1964. 511 pages. Illustrated, references, index. Price $25.00.**

This beautiful volume contains the papers and discussion of the International Symposium on Ocular Tumors, sponsored by Baylor University College of Medicine in 1962. The book has been divided into four sections—tumors of the conjunctiva and eyelid, retinoblastoma, pigmented intraocular tumors, and orbital tumors. We find here, well edited and illustrated, the most recent information regarding the incidence, clinical and pathological diagnosis, and management of ocular and adnexal neoplasma.

This book contains a complete list of references, and would be of value to the pathologist, neurosurgeon, and ophthalmologist.

William S. McClanahan, M.D.
Minneapolis, Minnesota

nicotron™ Nicotinic Acid and Aminoacetic Acid (Glycine)

Like Radiant Sun

Warms Cold Hands and Feet

nicotron™

NIACIN + AMINOACETIC ACID (Glycine)

increases and sustains peripheral blood flow (1-2)

INDICATIONS: Poor circulation causing cold hands and feet or pain on walking. For the more serious peripheral vascular disturbances such as . . . Raynaud's Disease, Meniere's Syndrome, intermittent claudication, diabetes, post-phlebitis syndrome, leg ulcers due to venostasis and chronic thrombophlebitis.

DOSAGE: 1 or 2 teaspoonfuls or 1 or 2 tablets 3 times a day before meals. The feeling of warmth and tingling of the skin is a desirable effect. If this reaction is too pronounced reduce dosage.

CONTRAINDICATIONS: There are no known contraindications.

SUPPLIED: 8 oz. bottles and bottles of 100 chew-tabs.

FORMULA: Each teaspoonful (5ml.) contains:
Nicotinic Acid .... 75 mg.
Glycine ....750 mg.
in a palatable Sherry Wine Base
Alcohol 5%
Each lemon flavored chew-tab contains:
Nicotinic Acid .... 75 mg.
Glycine ....750 mg.

Notice of Public Hearing
Minnesota State Board of Medical Examiners

"Notice is hereby given, pursuant to the provisions of Minnesota Statutes, 1961, S 15.0412, that the Minnesota State Board of Medical Examiners will hold a public hearing on Saturday, February 13, 1965, at 10 o'clock, A.M., in the auditorium of the State Office Building, Saint Paul, Minnesota, on the adoption of proposed substantive rules and regulations pertaining to professional corporations and to the practice of medicine and surgery, osteopathy, massage, physical therapy and midwifery, and of procedural rules and regulations pertaining to the hearing of contested cases before the Minnesota State Board of Medical Examiners.

Copies of the proposed procedural and substantive rules and regulations are available from the Secretary of the Minnesota State Board of Medical Examiners, 230 Lowry Medical Arts Building, Saint Paul, Minnesota, 55102.

Interested persons are invited to attend and submit data or views orally or in writing.

Dated at Saint Paul, Minnesota, this 23rd day of November, 1964.

By Order of the Minnesota State Board of Medical Examiners

J. P. Medelman M.D.

Secretary-Treasurer"

Rules and Regulations Pertaining to the Practice of Medicine, Surgery, Osteopathy, Physical Therapy, Massage and Midwifery, Proposed by the Minnesota State Board of Medical Examiners on November 19, 1964, Pursuant to Authority Conferred by Minnesota Statutes Annotated, Sections 147.01, 148.30-148.511, inclusive, 148.65-148.78, inclusive, and Sections 15.0411-15.0415, inclusive.

The following rules are adopted to carry out the purpose and intent of M.S.A., c. 147, §§ 148.30-148.511, inclusive, and 148.65-148.78, inclusive.

Rule 1. Definitions

1.01 As used in M.S.A., c. 147, and M.S.A., §§ 148.30-148.511, inclusive, and 148.65-148.78, inclusive, the terms herein defined shall have the following meanings:

1.011 "Minor surgery," as used in M.S.A., § 147.031, subd. 2, relating to the practice of osteopathy shall be construed to include all surgical procedures excepting: (a) those involved in incision for the opening of a natural body cavity, (b) open reduction of bone fractures, (c) the amputation of an extremity or an appendage, (d) the removal of any gland or organ or part thereof, or (e) any plastic surgery.

1.012 "Anesthetics," as used in M.S.A.,

Continued

§ 147.031, subd. 2, shall mean and include any agent used to produce topical, local, or general anesthesia. Such agents shall include, but shall not be limited to, the following: cyclopropane, ether, ethylene, chloroform, pentothal, barbiturates, nitrous oxide, cocaine, procaine, or any other agent intended to produce a like effect.

1.013 "Narcotics," as used in M.S.A., § 147.031, subd. 2, shall have the meaning ascribed to the term "narcotic drugs" by 26 U.S.C.A., § 4731, and by M.S.A., § 618.01, subd. 14. A narcotic drug includes, but shall not be limited to, the drugs specifically referred to in 26 U.S. C.A., § 4731, M.S.A., § 618.01, subd. 14, any compound derivative or preparation of the same, and any substance having an addiction-forming or addiction-sustaining liability similar to any of the same or capable of conversion into a drug having such addiction-forming or addiction-sustaining liability.

1.014 "Antidote," as used in M.S.A., § 147.031, subd. 2, shall mean any agent used to counteract the effects of a poison.

1.015 "Antiseptics," as used in M.S.A., § 147.031, subd. 2, shall mean any chemical or biological agent used to destroy or inhibit the growth and development in living tissue of microorganisms, and includes, but shall not be limited to, antiseptic agents defined as such in the official United States Pharmacopoeia, or registered and regulated for distribution under 21 U.S.C.A., §§ 351-357, inclusive.

1.016 The "Board" as used in these regulations shall mean Minnesota State Board of Medical Examiners.

1.017 The "Examining Committee" as used in these regulations shall mean the State Examining Committee for Physical Therapists created by M.S.A., § 148.67.

Rule 2. Application for Licensure for Medicine and Surgery

2.01 *Application.* An application for admission to a licensing examination to practice medicine shall be filed with the Board as hereinafter prescribed. If the Board finds that the application is complete and that all of the requirements of M.S.A., § 147.02, and of these regulations have been met, it shall advise the applicant of the date and place of the examination.

2.02 Such application shall be submitted on forms prepared by the Board and shall include the following information:

2.021 Original or certified copy of diploma from a medical or osteopathic college, as the case may be, duly accredited by the Board, indicating that the applicant has satisfactorily completed a course of study acceptable to the Board and that he has received from such college the degree of Doctor of Medicine, Bachelor of Medicine, Bachelor of Medicine and Surgery, or Doctor of Osteopathy.

2.022 Evidence, satisfactory to the Board, that the applicant has satisfactorily completed at least twelve (12) months of graduate training in a hospital approved by the Board.

2.023 A certificate of registration in the basic sciences issued by the Minnesota State Board of Examiners in the Basic Sciences.

2.024 A certificate of good moral character signed by two persons licensed by any recognized and accredited licensing authority within the United States or Canada to practice medicine and surgery.

2.025 An unmounted recent photograph of applicant with an affidavit on the reverse side thereof made by the applicant that the photograph is that of the applicant.

2.026 Such other information as the Board shall, from time to time, deem necessary in order to evaluate the qualifications of the applicant.

2.03 *Hearing on Applications.* An applicant whose credentials are determined by the Board to indicate ineligibility for examination shall be notified of such determination and the grounds therefor and may file with the Board a formal petition setting forth such grounds as he may desire in support of his eligibility. The Board shall, after due consideration of such petition, determine the merits of the petition and forthwith notify the applicant of its decision.

2.04 All applications for examination must be fully completed and forwarded to the Secretary of the Board, postmarked not later than thirty (30) days before the date of the examination.

Rule 3. Conduct of Examinations

3.01 Examinations shall be both written and oral. A written examination shall be given in surgery, medicine, materia medica, pediatrics, eye, ear, nose and throat, obstetrics, gynecology, and such other branches as the Board may from time to time determine.

3.02 Licensing examinations shall be conducted in accordance with the following rules, and any candidate violating such rules may be dismissed and barred from taking the examination, or may be otherwise disciplined.

3.021 During the written examination no applicant shall communicate with any other applicant in any way except with the express permission of the person or persons conducting the examination.

3.022 An applicant shall not bring books or help of any kind into the examination room.

3.03 *Grading of the Examination.* A grade of 75 shall be the passing grade. A minimum general average of 75 in all subjects shall constitute a grade satisfactory for licensure. An applicant may fall below 75 in one subject and still be licensed by the Board. If an applicant falls below 75 in more than two subjects, it shall constitute a failure and require that the applicant retake the entire examination with passing grades in order to be eligible for licensure. An applicant failing two subjects may retake the two subjects at the next examination and upon receiving a minimum grade of 75 in each may be eligible for licensure.

3.04 Upon the conclusion and grading of the examination, the Board shall prepare a report of the examination results, and shall act on the report at its next meeting. The Secretary of the Board shall notify the applicant of the action of the Board on his application and examination.

Rule 4. License by Reciprocity to Practice Medicine and Surgery

4.01 An application for a license to practice medicine and surgery, without written examination, in accordance with M.S.A., § 147.03, may be made by any physician duly licensed by an accredited state licensing board or agency.

4.02 Such application shall be submitted on forms prepared by the Board and shall include the following information:

4.021 An original or certified copy of all of applicant's then current licenses, including the license originally obtained by examination, together with evidence at the time of submission that all of the same are in good standing.

4.022 Original or certified copy of certificate of registration in the basic sciences issued by The Minnesota State Board of Examiners in the Basic Sciences.

4.023 Original or certified copy of diploma from a medical or osteopathic college, as the case may be, duly accredited by the Board, indicating that the applicant has satisfactorily completed a course of study acceptable to the Board, and that he has received from such college the degree of Doctor of Medicine, Bachelor of Medicine, Bachelor of Medicine and Surgery or Doctor of Osteopathy.

4.024 Evidence, satisfactory to the Board, that the applicant has satisfactorily completed at least twelve (12) months of graduate training in a hospital approved by the Board.

4.025 An unmounted recent photograph of applicant with an affidavit on the reverse side thereof made by the applicant that the photograph is that of the applicant.

4.026 A certificate of good moral character signed by two persons licensed by any recognized and accredited licensing authority within the United States or Canada to practice medicine and surgery.

4.027 Such other information as the Board shall, from time to time, deem necessary in order to evaluate the qualifications of the applicant.

Continued

Rule 5. License by Endorsement without Examination to Practice Medicine and Surgery

5.01 An application for a license to practice medicine and surgery by endorsement, without examination, may be made by any applicant who has passed an examination given by the National Board of Medical Examiners, the National Board of Examiners for Osteopathic Physicians and Surgeons, or by the appropriate board or agency of any state or country which the Board may from time to time determine to be acceptable, as provided in M.S.A., § 147.03; provided, however, that the Board may require the applicant to be examined in such subjects which, in the opinion of the Board, have not been satisfactorily covered, and may require the applicant to pass an oral examination.

5.02 Such application shall be submitted on forms prepared by the Board and shall show the information required by Rules 4.022 through 4.026, inclusive, and in addition thereto, the original or certified copy of the certificate or diploma from the appropriate national or state board or agency, as referred to in Rule 5.01 hereof, evidencing satisfactory completion of the examination therein referred to.

Rule 6. Temporary Permits to Practice Medicine and Temporary Certificates for Graduate Training

6.01 Applications for a temporary permit to practice medicine, pursuant to the provisions of M.S.A., § 147.02, shall be submitted on forms prepared by the Board and shall include the information required by Rule 4.02.

6.02 An application for a temporary certificate for graduate training, pursuant to the provisions of M.S.A., § 147.16, shall be submitted on forms prepared by the Board, which shall include the following information:

6.021 Original or certified copy of birth certificate.

6.022 Evidence of good moral character satisfactory to the Board.

6.023 Original or certified copy of degree, certificate or diploma from a school approved by the Board or evaluating agency recognized by the Board, evidencing satisfactory completion of a course of study as described in M.S.A., § 147.02.

6.024 In the case of an applicant whose course of study was completed at a school outside of the United States or Canada, evidence satisfactory to the Board that the school or college issuing the degree is approved by the licensing authority of the jurisdiction or country in which such medical or osteopathic school is located.

6.025 Original or certified copy of license to practice medicine in all of its branches in the state, territory or foreign country in which applicant resides or, if applicant is not so licensed, evidence satisfactory to the Board that applicant has passed an examination, or is eligible therefor, which is substantially equivalent to the examination given by the Board to applicants for a license to practice medicine in all of its branches in Minnesota.

6.026 Original or certified copy of certificate of registration in the basic sciences issued by The Minnesota State Board of Examiners in the Basic Sciences.

6.027 In the case of an applicant for residency training, evidence satisfactory to the Board that said applicant has completed at least twelve (12) months of hospital training as an intern in a hospital acceptable to the Board.

6.028 The name and location of the hospital at which such graduate training will be taken, and evidence that the hospital has accepted the applicant for training.

6.03 Upon issuance of a temporary certificate for graduate training, the holder may take postgraduate training in a teaching hospital within the State of Minnesota approved for resident training by the Board.

6.04 The holder of such certificate may perform those services incident to the training prescribed by the approved hospitals while acting under the direction of a person licensed to practice medicine and surgery in this state; provided, however, that no fee or remuneration of any kind shall be collected by the holder of such certificates from any patients treated by him; and, provided, further, that said holder of the certificate shall confine his training and practice to the hospital or group of hospitals designated in his original application.

Rule 7. Requirements for Licensure of Foreign Graduates in Medicine and Surgery

7.01 A graduate of a foreign medical school may apply for licensure to practice medicine and surgery in Minnesota, in accordance with M.S.A., § 147.02, by filing with the Board an application on forms provided by the Board, which forms shall include the following information:

7.011 The information required by Rules 2.023, 2.025 and 2.026.

7.012 Evidence satisfactory to the Board that the applicant is a graduate of a foreign medical school and is the holder of an approved diploma or degree recognized by the Board as evidencing a level of training from said approved foreign medical school commensurate with the medical training required by approved medical schools in the United States.

7.013 In the event that the applicant is not a citizen, he shall submit with his application evidence that he has made a declaration of intent to become a citizen of the United States.

7.014 Original, or certified copy, of his license to practice medicine and surgery in the foreign country, issued by the school from which he graduated or by the appropriate licensing body of the country in which he was originally licensed.

7.015 Evidence that the applicant, at the time of his application, is the holder of a valid license to practice medicine and surgery in the foreign country in which he is then residing.

7.016 Evidence of good moral character satisfactory to the Board.

7.017 Evidence of satisfactory completion of two (2) years training in an institution in Minnesota approved by the Board, or training, in the opinion of the Board, equivalent thereto.

Rule 8. Procedure for Licensure to Practice Medicine and Surgery by Persons Licensed to Practice Osteopathy

8.01 Any person licensed to practice osteopathy in this state under M.S.A., §§ 148.11 to 148.16, inclusive, may apply to this Board to be examined for licensure to practice medicine and surgery by filing with the Board an application on forms provided by the Board setting forth the date on which the applicant was licensed to practice, the number of years and place or places in which he has practiced.

8.02 The applicant, prior to licensure to practice medicine and surgery, shall be required to pass an examination in those subjects described in Rule 3.01 hereof in which the applicant has not previously been examined.

8.03 All applications, together with supporting credentials, shall be completed and filed with the Secretary of the Board at least thirty (30) days prior to the examination.

8.04 *Grading of the Examination.* A grade of 75 is considered to be the passing grade. A minimum general average of 75 in all subjects constitutes a grade satisfactory for licensure. An applicant may fall below 75 in one subject and still be licensed by the Board. If an applicant falls below 75 in more than two subjects, it shall constitute a failure and require that the applicant retake the entire examination with satisfactory grades in order to be eligible for licensure. An applicant failing two subjects may retake the two subjects at the next examination and upon receiving a minimum grade of 75 in each may be eligible for licensure.

Rule 9. Physical Therapy—Regulations Governing Registration and Practice

9.01 *Application.* An application for admission to a registration examination to practice physical therapy shall be filed with the Board as hereinafter prescribed. If the Board finds that the application is complete and that all of the requirements of the statute and of these regulations have been met, it shall advise the applicant of the date and place of the examination.

9.02 The application shall require the applicant to submit the following information:

9.021 Original or certified copy of birth certificate.

9.022 Original or certified copy of high

Continued

school diploma or evidence of equivalent education.

9.023 Original or certified copy of diploma, degree or certificate, or evidence satisfactory to the Board, indicating that the applicant has satisfactorily completed an approved curriculum in physical therapy as provided in M.S.A., § 148.70(d) and has graduated from a school of physical therapy approved by the Board and having standards of education and training substantially equivalent to the standards and training of the University of Minnesota.

9.024 Evidence, satisfactory to the Board, that the applicant is of good moral character.

9.025 An unmounted recent photograph with the affidavit of the applicant on the reverse side thereof that the photograph is that of the applicant.

9.03 An applicant, prior to registration, shall be examined in the subject matter described in M.S.A., § 148.70(d), and a listing of the subjects to be covered shall be made available by the Board to the applicant. Such examination may be oral, written, or both, and shall be conducted by the Board with the assistance of the State Examining Committee.

9.04 The Board may register as a physical therapist in this state without examination any person who presents evidence satisfactory to the Board of having passed an examination in accordance with the provisions of M.S.A., § 148.72, subd. 2, administered by a duly accredited examining agency. An applicant for registration without examination shall submit on forms provided by the Board the following information:

9.041 Original or certified copy of high school diploma, transcript of high school credits, or evidence of equivalent education.

9.042 Original or certified copy of diploma, degree or certificate of completion of an approved course in physical therapy.

9.043 Original or certified copy of birth certificate.

9.044 Original or certified copy of current license or certificate to practice physical therapy, if any, issued by the duly accredited examining agency of the state or foreign country from which the applicant is seeking registration without examination.

9.04 Unmounted recent photograph of applicant with an affidavit on the reverse side thereof made by the applicant that the photograph is that of the applicant.

9.04 A recommendation of good moral character by one physician and one physical therapist, each duly registered to practice medicine and physical therapy in the United States or Canada.

9.04 Complete transcript or transcripts of pre-professional and professional credits, each bearing the seal of the school of issuance, said transcripts to be forwarded directly to the Board from the school of issuance.

9.05 *Supervision and control over treatment—definitions.* In order to carry out the requirements of M.S.A., § 148.65, subd. 2, the terms herein defined shall have the following meanings:

9.051 "Prescription," as used in M.S.A., § 148.65, subd. 2, shall mean a written order signed by a physician duly licensed to practice medicine and surgery in this state directing that the physical therapist administer to the physician's patient a specified course of physical therapy, and containing such other orders, directions, and information, as the physician may deem necessary, to inform the physical therapist of the nature and extent of the treatment.

9.052 "Direct supervision" within the meaning of M.S.A., § 148.65, subd. 2, shall mean:

9.0521 a course of physical therapy under prescription, as defined in the foregoing paragraph, administered to a patient by a physical therapist employed by a physician or medical facility approved by the Board;

9.0522 examination, during the course of prescribed physical therapy, by a physician at such times and in such manner as the physician shall deem necessary to insure such change in the course of treatment as may be indicated;

9.0523 a registered physical therapist shall not, without the express direction of a physician duly licensed to practice medicine and surgery in the State of Minnesota, initiate, change, or terminate treatment; provided, however, in the case of emergency, such rule shall not prohibit a registered therapist from changing or terminating treatment which it appears that the patient cannot tolerate and, provided further, that the attending physician is notified immediately of such action.

9.053 Every registered physical therapist who shall annually renew his registration as required by M.S.A., § 148.73 shall indicate in each renewal, on forms provided by the Board, the name of his then current employer and place of employment.

Rule 10. Regulations Governing the Licensing and Practice of Masseurs and Masseuses

10.01 *Application for Licensure.* An application for admission to a licensing examination to practice massage as provided by M.S.A., § 148.36, shall be filed with the Board as hereinafter prescribed. If the Board finds that the application is complete and that all of the requirements of the statute and of these regulations have been met, it shall advise the applicant of the time, date and place of the examination.

10.02 The application shall be made on forms provided by the Board and shall require the applicant to submit the following information:

10.021 Original or certified copy of birth certificate.

10.022 Original or certified copy of high school diploma, transcript of high school credits, or evidence of equivalent education.

10.023 Original or certified copy of diploma, degree or certificate, or evidence satisfactory to the Board, indicating that the applicant has satisfactorily completed an approved course of training complying with the provisions of M.S.A., § 148.37.

10.024 Evidence, satisfactory to the Board, that the applicant is of good moral character.

10.025 An unmounted recent photograph with the affidavit of the applicant on the reverse side thereof that the photograph is that of the applicant.

10.03 An applicant, prior to registration, shall be examined in the subject matter described in M.S.A., § 148.38, and a listing of the subjects to be covered shall be made available by the Board to the applicant prior to examination. Such examination may be oral, written, or practical, and shall be conducted by the Board with the assistance of such experts as the Board may select, who are skilled in the art and science of massage, and who are duly licensed to practice massage in this state.

10.04 The Board, in its discretion, may issue a license to practice massage in this state without examination to any person holding a license from any other state or foreign country whose requirements for such license, as determined by the Board, are equivalent to those of the State of Minnesota. An applicant for registration without examination shall submit, on forms provided by the Board, the following information:

10.041 Original or certified copy of birth certificate.

10.042 Original or certified copy of high school diploma, transcript of high school credits, or evidence of equivalent education.

10.043 Original or certified copy of diploma, degree or certificate of completion of an approved course in massage.

10.044 Original or certified copy of license or certificate to practice massage issued by the state or country from which the applicant is seeking reciprocal licensure.

10.045 Unmounted recent photograph of applicant with an affidavit on the reverse side thereof made by the applicant that the photograph is that of the applicant.

10.046 Evidence, satisfactory to the Board, that the applicant is of good moral character.

Rule 11. Regulations Governing Practice of Midwifery

11.01 *Definition of Midwifery:* As used in M.S.A., § 148.30, the practice of midwifery includes the furthering or undertaking by any person to assist or attend a woman in normal pregnancy and childbirth, but shall not include the use of any instrument at a childbirth, except such instrument as is necessary in severing the umbilical cord, nor does it include the assisting of childbirth by any artificial, forcible, or mechanical means, nor the removal of adherent placenta, nor the administering, prescribing, advising, or employing, either before or after any childbirth, of any drug, other than a disinfectant or cathartic.

11.02 An application for admission to a licensing examination to practice midwifery in this state shall be filed with the Board as hereinafter prescribed. If the Board finds that the application is complete and that all of the requirements of the statute and of these regulations have been met, it shall advise the applicant of the date and place of the examination.

11.03 The application shall require the applicant to submit the following information:

11.031 Original or certified copy of high school diploma or evidence of equivalent education.

11.032 Original or certified copy of diploma, degree or certificate, or evidence satisfactory to the Board, indicating that the applicant has satisfactorily completed an approved curriculum in midwifery in an approved school or maternity hospital recognized by the Board.

11.033 Evidence, satisfactory to the Board, that the applicant is of good moral character.

11.034 An unmounted recent photograph with the affidavit of the applicant on the reverse side thereof that the photograph is that of the applicant.

11.04 The examination shall be both oral and written and shall include the following subjects: anatomy of the pelvis and female generative organs; physiology of menstruation; diagnosis and management of pregnancy, fetal presentation and position; mechanism and management of normal labor; management of the puerperium; injuries to the genital organ following labor; sepsis and asepsis in relation to labor; special care of the bed and lying-in room; hygiene of the mother and infant; asphyxiation, convulsions, malformation and infectious diseases of the newborn; cause and effects of ophthalmia neonatorum; abnormal conditions requiring attendance of a physician.

11.05 The Board may revoke or refuse to renew the license of any midwife for unprofessional or dishonorable conduct which shall include but not be limited to the following:

11.051 The conviction of a crime of criminal abortion or crimes involving moral turpitude.

11.052 Neglect or refusal to promptly make proper returns to a health officer or health department of births, of a puerperal, contagious or infectious disease.

11.053 Failure promptly to secure the attendance of a duly licensed physician in case of miscarriage, hemorrhage, abnormal presentation or position, retained placenta, convulsions, prolapse of the cord, fever during parturient stage, inflammation or discharge from the eyes of the newborn infant, or whenever any abnormal or unhealthy symptoms appear either in the mother or infant during pregnancy, labor, or the puerperium.

Rules and Regulations Pertaining to Professional Corporations, Proposed by the Minnesota State Board of Medical Examiners on November 19, 1964, Pursuant to Authority Conferred by Minnesota Statutes Annotated, Sections 319.01 to 319.23, inclusive, and Sections 15.0411-15.0415,, inclusive.

The following rules are adopted to carry out the purpose and intent of M.S.A., §§ 319.01 to 319.23, inclusive.

Rule 12. Regulations Governing Establishment and Operation of Professional Corporations

12.01 *Application for Registration.* A professional corporation organized in accordance with the provisions of M.S.A., §§ 319.01 to 319.23, inclusive, shall, before commencing operation or rendering professional service, make application to the Board for a certificate of registration as hereinafter prescribed. If the Board finds that the application is complete and that all of the requirements of the statute and of these regulations have been met, it shall issue to the applicant a certificate of registration which shall constitute the authority of the professional corporation to commence rendering professional services.

12.02 The application shall be submitted on forms prepared by the Board, which forms shall require the applicant to submit the following information:

12.021 Certified copy of articles of incorporation and by-laws and all existing amendments filed in the office of the Secretary of State.

12.022 The address of the registered office of the corporation and the name of its proposed registered agent, if any, for service of process.

12.023 The name or names and respective addresses of the directors and officers of the corporation.

12.024 In the case of a corporation organized under M.S.A., c. 301, a statement of the aggregate number of issued shares, itemized by classes and the person or persons to whom issued.

12.025 In the case of a corporation organized under M.S.A., c. 317, a statement of the names of the members of the corporation.

12.026 A description of the nature of the professional services and ancillary services, if any, to be provided by the corporation.

12.027 The location or locations of the premises at which the applicant corporation proposes to provide professional services.

12.028 A statement listing the name or names of employees, other than members or shareholders of the corporation, who are licensed under M.S.A., c. 147, to practice medicine and surgery within the State of Minnesota.

12.03 The application shall be executed by the corporation by its president and secretary and shall be forwarded to the Board, together with a registration fee in the amount of One Hundred Dollars ($100.00).

12.04 If the Board finds, upon investigation, that the application conforms to all the requirements of M.S.A., c. 319, and the regulations issued thereunder, the Board shall issue a certificate of registration indicating thereon the establishment or establishments at which said certificate of registration shall authorize the applicant to provide professional services.

12.05 Upon the issuance of a certificate of registration by the Board, the corporation shall be authorized to provide the professional services described in its application.

12.06 *Annual Renewal of Registration.* On or before December 1 of each year, each registered corporation shall submit, on forms provided by the Board, an application for the renewal of its certificate of registration. Such application shall be accompanied by a fee in the amount of Twenty-five Dollars ($25.00). The Board shall require the applicant to submit such information as will permit the Board to determine that the applicant corporation is in compliance with the requirements of M.S.A., §§ 319.01 through 319.23, inclusive, and the regulations issued thereunder.

12.07 *Denial, Suspension or Revocation of Certificate of Registration.* The Board may suspend or revoke any certificate of registration in accordance with the provision of M.S.A., § 319.12, provided, however, that such action shall be taken only after written notice and opportunity for hearing thereon in the manner and in accordance with the procedures adopted by the Board governing the conduct of contested cases.

Continued

12.08 *Change of Location.* A certificate of registration issued hereunder shall be applicable only at the location or locations indicated therein. A corporation desiring to change the location or locations of any establishments to which such certificate of registration is applicable shall, at least sixty (60) days prior to such change of location, file with the Board a notice of intent to change location of registered establishment. Such notice shall include the following information:

12.081 The name of the registered corporation.

12.082 The location or locations for which the current certificate of registration is applicable.

12.083 The proposed new location at which the corporation intends to provide professional services.

12.084 A statement showing the names of the shareholders, members, or employees who will provide professional services at the proposed new location.

The Board shall, after receipt of such notice and approval, issue the certificate of registration applicable to the new location at which the corporation intends to provide professional services.

12.09 *Changes in Shareholders, Members or Licensed Employees of Corporation.* Whenever a professional corporation, organized under M.S.A., c. 319, intends to admit to the corporation a new shareholder, member or licensed employee, the corporation shall, at least thirty (30) days prior thereto, notify the Board of its intended action, indicating thereon the identity, state of current licensure to practice medicine and such other information as the Board may require to permit it to investigate and determine whether such new shareholder, member or licensed employee is qualified to practice medicine in the State of Minnesota.

12.10 *Death or Disqualification of Shareholder or Member.* Each corporation holding a certificate of registration issued under M.S.A., c. 319, shall, in the event of death or disqualification of one of its shareholders, members, or employees licensed under M.S.A., c. 147, notify the Board within thirty (30) days thereafter, and shall, in the case of a shareholder or member, prior to the expiration of ninety (90) days from the date of death or disqualification, advise the Board concerning the transfer or other disposition of the shares of such deceased or disqualified shareholder or member.

Procedural Rules and Regulations Proposed by the Minnesota State Board of Medical Examiners on November 19, 1964, Pursuant to Authority Conferred by Minnesota Statutes Annotated, Sections 15.0411-15.0415, inclusive.

The following procedural rules are adopted to carry out the purpose and intent of M.S.A., §§ 15.0411-15.0415, inclusive, and govern the conduct of all proceedings defined as a contested case within the meaning of M.S.A., § 15.0411, subd. 4.

Rule 13. Procedural Rules

13.01 *Definitions.* For the purposes of these rules, the terms defined in this section have the following meanings:

13.011 "Board" means the Minnesota State Board of Medical Examiners or any member or members thereof authorized by law to adjudicate contested cases.

13.012 "Contested Case" means a proceeding before the Board in which the legal rights, duties or privileges of specific parties under the provisions of any statute granting jurisdiction to the Board are required by law or constitutional right to be determined after a Board hearing.

13.013 "Party" includes the Board, the respondent, and any person, other than a member of the Board in his official capacity, who has been permitted to appear in the proceeding.

13.014 "Respondent" means any person or professional corporation against whom an accusation or charge has been filed pursuant to any statute granting jurisdiction to the Board, or any person or professional corporation which is subject to a dispute concerning any legal rights, duties or privileges granted or conferred thereby.

13.02 *Revocation, Suspension, etc.* A hearing to determine whether a right, license or privilege should be revoked, suspended, limited or conditioned, shall be initiated by filing an accusation. The accusation shall be a written statement of charges which shall set forth in ordinary and concise language the acts or omissions with which the respondent is charged and shall be in sufficient detail to enable the respondent to prepare his defense. It shall specify the statutes and rules which the respondent is alleged to have violated, but shall not consist merely of charges phrased in the language of such statutes and rules. The accusation shall be verified by a member of the Board. The verification may be on information and belief.

13.03 *Hearing on Issuance or Renewal of License.* A hearing to determine whether a right, license or privilege should be granted, issued or renewed shall be initiated either by the Board or by the applicant by filing a statement of issues. The statement of issues shall be a written statement specifying the statutes and rules with which the applicant must show compliance by producing proof at the hearing and, in addition, any additional matters which have come to the attention of the initiating party and which would bear upon the issues presented. The statement of issues shall be verified by the initiating party. The verification may be on information and belief. If the Board is the initiating party, the statement of issues shall be served in the same manner as an accusation. If the applicant is the initiating party, the statement of issues shall be served on the Board by registered or certified mail, addressed to the Board at 230 Lowry Medical Arts Building, Saint Paul, Minnesota, 55102. If the initiating party is the Board, the applicant may request a hearing in the manner provided in Rule 13.05 hereof. If the initiating party is the applicant, the statement of issues shall be considered as a request for hearing, and a hearing shall be granted to applicant within thirty (30) days after service upon the Board of the statement of issues.

13.04 *Service of Accusation; Request for Hearing; Form, Manner and Proof.*

13.041 Upon the filing of the accusation, the Board shall serve a copy thereof on the respondent as provided in 13.043 hereof. In addition to the matters to be included in the accusation as set forth in 13.02 hereof, the Board may include with the accusation any additional information which it deems appropriate. The copy of the accusation shall include or be accompanied by the statement that respondent may request a hearing by notifying the Board thereof within fifteen (15) days after service upon him of the accusation, and that failure to do so will constitute a waiver of his right to a hearing.

13.042 The statement to respondent shall be substantially in the following form:

> Unless a written request for a hearing, signed by you or on your behalf is delivered or mailed to the Minnesota State Board of Medical Examiners at 230 Lowry Medical Arts Building, Saint Paul, Minnesota, 55102, within fifteen (15) days after the accusation was personally served on you or mailed to you, the Minnesota State Board of Medical Examiners may proceed upon the accusation without a hearing.

13.043 If the respondent is a resident of the State of Minnesota and can be found therein, the accusation and all accompanying information shall be served upon respondent personally in the manner provided by law for the service of a summons in a civil action. If the respondent is not a resident of the State of Minnesota, or if the respondent is a resident of the State of Minnesota but cannot be found therein, the accusation and all accompanying information shall be served upon respondent by registered or certified mail, addressed to the most recent address theretofore furnished by the respondent to the Board, and the same shall be deemed received by respondent five (5) days after having been deposited in the United States mail, post-

Continued

age prepaid, addressed to such address. The filing by respondent of a request for hearing or his appearance in the proceeding shall constitute a waiver of any defect in such service. Service may be proved by the affidavit of the person making the same.

13.044 Filing of a request for hearing shall be deemed a specific denial of all parts of the accusation not expressly admitted. Failure to file such a request shall constitute a waiver of respondent's right to a hearing, but the Board, in its discretion, may nevertheless grant a hearing.

13.05 *Time and Place of Hearing.* The Board shall determine the time and place of the hearing, which shall be held within thirty (30) days after receipt by the Board of the request for hearing. The hearing shall be held in Saint Paul, Minnesota, at a place designated by the Board, unless the parties, by agreement, select another place within the State of Minnesota.

13.06 *Notice of Hearing.* The Board shall deliver or mail a Notice of Hearing to all parties at least ten (10) days prior to the hearing. The Notice of Hearing to respondent shall be substantially in the following form:

> You are hereby notified that a hearing will be held before the Minnesota State Board of Medical Examiners at (insert place of hearing) on the __ day of __________, 19____, at the hour of ________, ____M., o'clock, upon the charges made in the accusation served upon you. You may be present at the hearing, may be, but need not be, represented by counsel, may present any relevant evidence, and will be given full opportunity to cross-examine all witnesses testifying against you.

13.07 *Depositions for Use as Evidence in the Hearing.* On request of the respondent, or upon notice from the Board to the respondent, the Board may permit the testimony of any material witness, residing within or without the state, to be taken for use as evidence in the hearing, by deposition in the manner prescribed by law for such depositions in civil actions. The request or notice shall set forth the nature of the pending proceedings; the name and address of the witness whose testimony is desired; a showing of the materiality of his testimony; a showing that the witness will be unable to attend; and the Board shall, thereupon, forward a request to the witness to appear and testify before an officer named in the request.

13.08 *Conduct of Hearing.*

13.081 Every hearing in a contested case shall be presided over by a member of the Board. A case may be heard by six (6) or more members of the Board.

13.082 The attorney for the Board shall advise the member or members of the Board concerning the conduct of the hearing and rulings on the admission or exclusion of evidence and other matters of law.

13.083 Any member of the Board shall voluntarily disqualify himself and withdraw from any case in which he cannot accord a fair and impartial hearing or consideration. Any party may request the disqualification of any Board member by filing an affidavit, prior to the taking of evidence at a hearing, stating with particularity the grounds upon which it is claimed that a fair and impartial hearing cannot be accorded. The issue shall be determined by the other members of the Board. No Board member shall withdraw voluntarily or be subject to disqualification if his disqualification would prevent the existence of a quorum qualified to act in a particular case.

13.084 All proceedings at the hearing shall be reported in writing, and the Board shall prepare an official record, which shall include testimony and exhibits in each contested case, but it shall not be necessary to transcribe the record unless requested for purposes of rehearing or court review.

13.09 *Evidence.*

13.091 All evidence shall be taken only on oath or affirmation.

13.092 Each party shall have the right to call and examine witnesses; to introduce exhibits; to cross-examine opposing witnesses on any matter relevant to the issues even though that matter was not covered in direct examination; to impeach any witness regardless of which party first called him to testify; and to rebut the evidence against him. If respondent does not testify in his own behalf, he may be called and examined as if under cross-examination.

13.093 The Board may admit and give probative effect to relevant evidence which possesses probative value and shall not be bound by the technical rules relating to evidence and witnesses; provided, however, that the Board shall give effect to the rules of privilege recognized by law. Hearsay evidence may be used for the purpose of supplementing or explaining any direct evidence but shall not be sufficient in itself to support a finding unless it would be admissible over objection in civil actions. All evidence including records and documents (except tax returns and tax reports) in the possession of the Board of which it desires to avail itself shall be offered and made a part of the record in the case. Documentary evidence may be received in the form of copies or excerpts, or by incorporation by reference.

13.10 *Decision in Contested Case.*

13.101 No right, license or privilege shall be granted, issued, renewed, revoked, suspended, limited or conditioned except upon the affirmative vote of at least six (6) members of the Board.

13.102 Whenever, in a contested case, a member of the Board who has not participated in the hearing votes in the decision of the case, a final decision, if adverse to the respondent, shall not be made until a proposed decision, including the statement of reasons therefor, has been served on the respondent, and opportunity has been afforded to file exceptions and present argument to all of the members of the Board who are to render the final decision.

13.103 The respondent shall have the opportunity to present either oral or written argument and to present additional newly discovered evidence after the close of the record but prior to final decision.

13.104 Informal disposition of a contested case may be made in the manner prescribed by law.

13.11 *Form of decision; findings.* Every decision and order adverse to a party to the proceeding shall be in writing and shall contain a statement of findings or reasons, a determination of the issues presented, and the penalty, if any, or decision of the Board. The findings shall consist of a statement of the conclusions upon each contested issue of fact necessary to the decision. Parties to the proceedings shall be notified of the decision and order in person or by mail. A copy of the decision and order and accompanying statement of reasons together with proof of service shall be delivered or mailed, upon request, to the respondent or to his attorney of record.

13.12 *Effective date of decision; stay of execution; notification of suspension or revocation.*

13.121 The decision or order of the Board shall become effective immediately upon its service on respondent; provided, however, that the Board may, in its discretion, stay the enforcement of its decision pending appeal or reconsideration within thirty (30) days after said service.

13.122 The Board may, upon its own motion or upon petition by respondent, reconsider or grant a rehearing of any decision rendered in a contested case or may condition any such decision upon just and reasonable grounds.

13.123 The filing of a petition for review shall not automatically stay the enforcement of the Board decision.

Reason is the light, the sun, of the brain. It is the compass of the mind, the ever-constant Northern Star, the mountain peak that lifts itself above all clouds.

Perinatal Mortality Study

Severe Anemia in the Newborn*

Case Report

The 29-year-old mother of the infant under study was Group A, Rh positive, and this was her fifth pregnancy. She had had no difficulty during her other four pregnancies; her children are living and well. She had no illness during her present pregnancy; the only drugs she received were prenatal iron, calcium, and vitamin D capsules twice daily. About two to three days prior to labor at 38 weeks she felt something was wrong with the infant because fetal movements were markedly decreased. Rupture of the membranes occurred 28 hours prior to delivery, and labor lasted 11½ hours. A large bloody show occurred 30 minutes before delivery. The delivery was spontaneous ROA under pudendal block anesthesia. The placenta measured 18 cm. in diameter, weighed 420 grams, and 1/6 of the maternal surface was covered with a thick tenaceous mass of clotted blood indicating abruptio placenta.

At birth the male infant was pale and flaccid and weighed five pounds, 11 ounces. The respirations were gasping. There was no petechia or jaundice. The cord hemoglobin was reported 45 minutes after birth as 4.6 grams %, and the white blood count 30,750 per mm^3. with a differential of 63% diff. pmn., 6% stab., 1% immature cells, 27% lymph., 1% mono., and 2% eos. The mother's hemoglobin was 13.5 grams %. No tests were done to detect fetal hemoglobin in the mother's blood. The infant was given oxygen in an incubator. At one and one-half hours of age a pediatrician was called to see the infant, and he recommended that the child be sent to another hospital for care. At two hours of age the infant arrived at the second hospital. He was pale and gray-appearing; his respirations were 14 to 16 per minute and irregular; his heart rate was 100 per minute and regular; his hemoglobin, 4.2 grams %, hematocrit 17%. It was then decided to give him an emergency transfusion of fresh Group O, Rh negative blood. The umbilical vein was catheterized, and the venous pressure was less than 2 cm. of water. Fifty-eight cc. of whole blood was rapidly given, and the infant suddenly expired at four hours of age.

Autopsy revealed the infant to be pale and cyanotic with no jaundice present. The lungs showed massive atelectasis, and many of the alveoli were filled with epithelial squames, interpreted by the pathologist as evidence of intrauterine respiratory efforts. The heart, liver, spleen, adrenals, kidneys, and brain showed no petechiae and were found to be normal.

Comment

This case demonstrates anemia in the newborn and hemorrhage from the placenta associated with an abruptio placenta. The Ramsey County Perinatal Mortality Study Committee feels that the infant should have received emergency blood at 45 minutes of age when the cord hemoglobin was reported as 4.6 grams %, rather than after transfer to another hospital when the child was almost four hours of age. Blood should be given carefully, with constant monitoring of the venous pressure.

Discussion

Kendall[1] lists the following causes of anemia in the newborn infant:

"1. Blood group incompatibility
2. Hemorrhage from the placenta
3. Hemorrhage into or from the umbilical cord
4. Hemorrhage into body organs
5. Infections
6. Fetomaternal transfusion
7. Hemorrhage from one twin to another"

---

*Ramsey County Perinatal Mortality Study Committee.

Continued

Schaffer[2] states, "When anemia is the only or is the major presenting symptom at birth, its cause is apt to be found in excessive hemolysis or fetal hemorrhage. The anemia of infection is overshadowed by associated symptoms, since those infections which have been severe enough to produce serious anemia by the time of birth almost always have led to purpura, jaundice, hepatosplenomegaly and other signs. In the infant pale at birth one first searches for evidences of hemolytic disease (Coombs tests, direct and indirect, erythroblastosis, normoblastosis and reticulocytosis, urebilinuria and excessive urobilinogen in stools) and for its possible causes (Rh, ABO or other incompatibilities, circulation antibodies, red-cell or hemoglobin defects). We might repeat here once again that this search must be delayed if anemia is severe, until blood replacement and digitalis therapy shall have been accomplished, so that the heart will not fail while one is looking for causes. The bilirubin content of the blood probably will be found elevated during the first day if the disorder is hemolytic, but it need not be very high, and the liver and spleen are almost always enlarged.

"If no evidence of or causes for hemolysis can be found, one may entertain the considerably less common diagnosis of posthemorrhagic anemia. This may be difficult to prove. A history of maternal bleeding of unusual quantity or of unusually bright red color before or during delivery is significant. Also the presence of placenta previa or the history of delivery by cesarean section can be considered suggestive evidence in favor of fetal bleeding. The coincidental delivery of an identical twin supplies a possible locus where blood loss may have occurred. If all these have been lacking, one searches for evidence that fetal blood has entered the maternal blood stream.

"The posthemorrhagic anemic newborn is pale and may be shocked, but he is not apneic and his heart rate is more apt to be unduly rapid than unduly slow. The liver and spleen are not enlarged, nor are there any evidences of bleeding into the skin or elsewhere."

Summary

A case of severe anemia in the newborn and hemorrhage from the placenta associated with an abruptio placenta is presented, and the differential diagnosis of anemia in the newborn infant is discussed.

The Ramsey County Perinatal Mortality Study Committee feels that all infants with severe anemia at birth should receive immediate blood transfusion or exchange transfusion of fresh Group O, Rh negative compatible blood. This can be done through the umbilical vein. With life-threatening, severe anemia, sometimes it is necessary to give blood before the complete etiologic factors responsible for the anemia can be determined.

Cervical Cytology Survey

SAMUEL A. SMITH, M.D.*
Minneapolis, Minnesota

IT HAS often been said that not enough is being done to encourage the use of the pap smear as a routine test for cervical cancer. It is well known that, since its introduction some thirty years ago, acceptance has been slow. As the use of the smear as a routine diagnostic procedure has increased, however, the morbidity and mortality from cancer of the cervix has decreased. For example, the death rate in Minnesota was 40.0 per 1,000 in 1944 and 29.9 per 1,000 in 1963.

In the light of a growing awareness of the effectiveness of the smear, and the concern that more ought to be done to promote its routine use, it was decided to survey Minnesota physicians on the subject. It was anticipated that the results of the survey would encourage and increase the use of this diagnostic procedure.

Materials and Methods

The questionnaire and accompanying explanatory letter (Fig. 1) were developed.** The questionnaire was designed to separate responders into groups characterized by type of practice and routine use of the smear. It was arbitrarily decided to poll only obstetrician-gynecologists, internists, general practitioners, and general surgeons. A fifth category, "other," includes physicians who stated that they are in institutional or industrial medicine. As the initial questionnaires were returned, those indicating a type of practice other than the designated ones were eliminated.

Results

There were finally eighteen hundred thirty-five questionnaires completed and returned by physicians in the specified categories (Table 1). One thousand six hundred eighty-four physicians, or 91.8% of the responders

state that they examine and/or treat female pelvic complaints. It is this group of 1,684 physicians that this paper is concerned with. The lone gynecologist who reported that he did not examine or treat pelvic complaints stated that he acted only as a consultant; he did not complete the questionnaire (Table 2).

Use of the Smear as a Routine Test

One thousand two hundred and twenty-three physicians (72.6%) of the responders (1,684) who handle pelvic complaints state that they take routine pap smears. In this group are 93.1 per cent of the obstetrician-gynecologists, 67.0 per cent of the general practitioners, 89.8 per cent of the internists, and 72.2 per cent of the surgeons. It appears then that a significant number of those physicians who handle pelvic complaints take routine smears. Further questioning of these physicians reveals that 64.3 per cent of them feel that the first smear should be taken prior to age thirty; this group includes 73.2 per cent of the obstetrician-gynecologists and 65.6 per cent of the general practitioners. The earliest suggested age was 13 (Tables 3 and 4).

Frequency of Taking Smears

Eighty per cent of each group advocate taking smears once a year (Table 5).

Use of the Smear as a Part of the Pre-partum Examination

The final question asked of those doing smears on a routine basis concerned use of the smear as part of the pre-partum examination. It has been advocated that the smear be a part of this examination since expectant mothers are a captive group. Four hundred twenty-five (34.8%) of those responding to this question (1,223) state that it is part of

their examination. It was assumed that no response to this question meant that the physician did not engage in obstetrics as part or all of his practice (Table 6).

Indications for Doing a Pap Smear

Those physicians who state that they did not take routine pap smears were questioned concerning their reasons for doing any smear at all. The choices were patient request, pathology on pelvic examination, symptoms of the genitourinary tract and pre and post-partum examination (Table 7). It is evident that patient request plays a significant role among these physicians, and the smear is often used as a primary diagnostic tool rather than as a screening device. One hundred per cent of the physicians in this group had two or more responses to this question.

Reasons for Not Doing Routine Smears

In this case the responders were given a choice of responses. The results are tabulated with respect to the frequency of response. It is evident (Table 8) that cost and low yield are major factors influencing this group in its decision not to do routine smears. According to statements made by many responders, the cost depends largely on the fee charged by the laboratories processing the smears. The suggestion was often made that the state establish a laboratory to process smears free or at cost.

What Do You Do When you Receive Other Than a Negative Report

The entire group of responders were asked what they did when they received a suspicious or positive report. The choice of response was any combination of biopsy (punch, cold cone, D and C), repeat smear, other. More than 90 per cent of the "other" was filled in by referral. The responses indicate a large combination of possible procedures (Table 9). It is evident from the responses that the majority of physicians answering this question favor repeating the smear.

Responders were then asked what their next step would be if they received a positive report. Again any combination of the choices was accepted, and as in the previous question there was a great number of possible combinations (Table 10).

Number of Smears Being Done

In an attempt to ascertain how many smears are being done in Minnesota each responder was asked to state how many smears he had done in the seven-day period

prior to receiving the questionnaire (Table 11).

Suggestions Regarding Improving the Pap Smear Program in Minnesota

Each responder was asked to make suggestions for improving the program. One hundred and fifty-one responders did not answer this question. Sixty-nine per cent (69.0%) of those responding suggest an expanded educational program aimed at both physicians and the laity. Other significant suggestions include: state subsidy for processing smears, and establishment of a state laboratory to do the processing for a nominal fee or free of charge. Frequent protests were made that there is no standard fee for smears, and fees from three to twelve dollars were quoted.

Conclusion

It would appear that this survey was fairly successful. It is quite evident from the responses that a fair number of Minnesota physicians whose practice involves handling of the female genital tract are aware of the usefulness of the smear. It would appear that they also recognize the need for an expanded effort to make this test available to more females in the state.

Requirements for Medical Degrees at Salernum

Candidates were required to be twenty-one years of age, and to produce proofs of having studied Medicine for seven years. As yet the degree thus obtained did not authorize one to practice indiscriminately in every department; for, if the candidate desired to be admitted to practice Surgery, it was required in addition that he should study Anatomy for one whole year. But every one, to whatever degree admitted, must first swear to be true and obedient to the Society of Physicians — to refuse all fees from the poor, *and to have no share of gains with apothecaries.* A book was then put into his hands — a ring upon his finger — his head was crowned with laurel, and he was dismissed with a kiss. (John Ordronaux)*

*Rapport, Samuel, and Wright, Helen: Great Adventures in Medicine. The Dial Press, New York, 1952, p. 75.

The Laryngoscope

Senor Manuel Garcia (1805-1906), who created the laryngoscope, was a singing-master who wanted to see how his larynx worked. The idea came to him out of a blue sky. With two mirrors it is possible to see round a corner, and the larynx is so far round a corner as to be normally invisible. Garcia bought his two mirrors, a little dental mirror with a long handle, which cost 6 francs, and a hand mirror. The dental mirror he placed firmly against his uvula, and what appeared there he saw in the hand mirror, which reflected a ray of light on to the dental mirror.*

Be humble or you'll stumble. — Dwight L. Moody

Harvey Cushing

(1869-1939)

It has been affirmed by many that the mantle of John Hunter fell upon Harvey Cushing, a life-long exponent of the experimental method. In the domain of neurological surgery, from the earliest mention of trephanning in the time of Hippocrates, to Galen, the first experimental neurologist, and following Ferrier's demonstration of the theory of cerebral localization in 1881, a great volume of experimental research on the brain and spinal cord was done. However, neurosurgery, as a specialty, was not born until the beginning of the present century. ". . . and it is unique in that it was largely the creation of two individuals . . . Sir Victor Horsley laid its foundations, and Harvey Cushing built the edifice of special technique and knowledge that today stands as one of the notable achievements of modern surgery."[1]

Born in Cleveland, of New England stock, from a family of distinguished doctors, Cushing studied at Yale and Harvard. After graduation he applied for a residency in Surgery at Johns Hopkins under Doctor William S. Halsted, which post he held for four years. After a year's study with Theodore Kocher and Hugo Kronecker in Berne, Switzerland, where he did his first work in experimental neurology, he returned to Johns Hopkins. He proposed to Doctor Halsted that he enter the field of neurology. His early mortality rate was extremely high. With utmost diligence and thoroughness, surmounting most of his operative difficulties, ". . .* he developed the method of precise localizing diagnosis for brain tumors and worked out the highly specialized technique for operating upon the brain. . . . The general principles of surgical technique that formed the basis of Cushing's methods were those of his great chief, Halsted . . . Cushing applied these principles to brain surgery with great skill. He controlled bleeding from the scalp by placing a tourniquet around it. For tumors of the sub-occipital region he devised the so-called cross-bow incision which has been the standard one ever since. . . . He introduced the practice of keeping a running record of the patient's blood pressure during the whole course of the operation in order to detect the development of shock — a practice which has since been adopted in all types of surgery. An amusing anecdote is told of Cushing's trials in the early days when he was introducing the blood pressure apparatus in the operating room. At a crucial point during one of his operations the patient showed signs of collapse and he ordered one of the nurses to get the blood pressure machine and find out what the pressure was. It was the custom to apply the apparatus to the patient's leg in those days. There was a long delay during which Cushing, absorbed as he was with difficulties in the operative field, had no time to pay attention to anything

else. Finally, he felt some encumbrance on one of his own legs and looking down found that the eager nurse had applied the apparatus to his leg rather than to the patient's."[2]

Cushing began to use experimental animal surgery early in his work at Johns Hopkins. By 1904 he was given a building. Doctor William H. Welch suggested that it be named after John Hunter, so it became the Hunterian Laboratory for Experimental Medicine and Surgery. From the day it opened . . . "the S.P.C.A. began camping on its trail. Frequently they slowed up the work — occasionally they stopped it completely — but it was never longer than a week, and efforts to close the laboratory permanently failed dismally. . . . From the beginning Cushing was extremely solicitous of the animals and impressed everyone that there would be no tolerance of cruelty or careless handling. All work was to be done on the highest scientific plane, and nothing should be done without proper and adequate anesthesia; problems had to have sense and reason; they all were to be properly supervised. . ."[3]

One of Cushing's former students who worked with him in the laboratory delineates him: "Among the many men who came to the Hopkins, achieved greatness and shed glamour and renown on the institution, Harvey Cushing must take high rank. . . . The world was his horizon, and properly so, because he was a many-sided man with an intellect of surprising quality. Greatness was literally written all over him — Consider this man . . . — thin, medium-sized, muscular, chiseled features, snapping eyes, quick-thinking, quick-acting, short-tempered, nervous, charming, sarcastic, inconsiderate, impatient, ruthless (depending on changing moods), jealous, lovable, selfish, domineering, demanding — he had a penetrating mind, stupendous ability, and there was nothing he couldn't do and do well once he decided to have a go at it."[4]

During those early years in Baltimore Cushing became close friends with William Osler, his next-door neighbor. From Osler he acquired his love of books, becoming a leading medical bibliophile. After Osler's death, Lady Osler selected Cushing to write her husband's biography. THE LIFE OF SIR WILLIAM OSLER, written in a reverent and masterly hand, is considered the outstanding medical biography of our time. This two-volume work won for Cushing the Pulitzer prize in 1926.

In 1912 Cushing was called to Harvard as Mosley professor of Surgery, and Surgeon-in-Chief to the newly constructed Peter Bent Brigham Hospital. During the next twenty years he accomplished his major work there, where his clinic for neurosurgery attained world renown. "He perfected his methods, accumulated a great mass of data concerning brain tumors, and trained a succession of young men who carried his teachings abroad and established neurosurgery as a speciality in the chief centers of medical education everywhere."[5]

Cushing gave nearly four years of service during World War I, serving first with a Harvard Unit. He organized and directed one of the base hospital units, and served as operating surgeon with the B.E.F. He was transferred to the Medical Headquarters of the A.E.F. as senior consultant in neurosurgery. With unsparing devotion to his work, he was sometimes on duty for sixteen hours at a stretch. This undoubtedly undermined his health for the rest of his life. His daily diary, FROM A SURGEON'S JOURNAL, was printed in book form. It is as vivid and informative as any contemporary document of the period. Three countries awarded him for his great work; the United States by the award of a Distinguished Service Medal, Great Britain by the Order of the Companion of the Bath, and France with the position, Officer of the Legion of Honor.

When Cushing retired from Harvard in 1932, he summarized his work in a monograph entitled, INTRACRANIAL TUMORS, NOTES UPON A SERIES OF TWO THOUSAND VERIFIED CASES WITH SURGICAL MORTALITY PERCENTAGES PERTAINING THERETO. He also wrote a series of articles and monographs on special forms of brain tumors. His short essays are considered gems of modern prose. Inspired by Osler, he became interested in Vesalius, continuing for forty years to collect everything available about him. He corresponded with many Vesalian scholars in this country and Europe. He spent the last years of his life assembling material for a Vesalian bibliography. A BIO-BIOGRAPHY OF ANDREAS VESALIUS was published posthumously.

Cushing's last post was at Yale, where he was Sterling Professor of Neurology, following which he became Emeritus Professor and Director of Studies in the History of Medicine. He donated to Yale his incomparable collection of books and manuscripts, including his Brain Tumor Registry. The historical division of the Yale Library is now the Cushing Library.

Cushing passed away in 1939 at the age of seventy. His pupils are carrying on brilliantly the work he originated. Some have formed a society which bears his name. Although numerous honors, awards and citations came to Cushing, those who knew him well say he would have liked best to have it said about him that he followed the highest tradition of our profession — that he never neglected anything that could bring comfort or benefit to a patient.

Doyle's Austerity

Sir Arthur Conan Doyle started in practice at Southsea with an empty villa, 4 pounds worth of second-hand furniture, a stock of drugs obtained on credit and 2 pounds cash. He found that he could live 'quite easily and well on less than a shilling a day.' Bread, bacon and tea were his staples, with an occasional saveloy. His young brother joined him to perform some of the chores and one day was able to record, 'We have vaxenated a baby and got hold of a man with consumption.' They also got hold of a man with epilepsy, whose fits kept them in butter and tea. 'Poor fellow,' writes Sir Arthur, 'he could never have realized the mixed feelings with which I received the news of a fresh outbreak.'*

Kindness — a language which the dumb can speak and the deaf can understand.
— C. N. Bovee

Of 425 patients with confirmed G.I. infections... 387 or 91.1% were treated successfully with Signemycin®

Note:
Loughlin and co-workers* achieved cure (absence of parasites) in all 100 of their patients with *chronic amebic colitis*. Feces became negative in all within the planned ten-day period of Signemycin administration. Upon re-examination of the feces six weeks later, the offending pathogen *(E. histolytica)* had reappeared in only 7 cases.

In Memoriam

Death is the crown of life. Were death denied, poor man would live in vain; to live would not be life; even fools would wish to die. — Young

JOHN LOWELL STENNES

Dr. John L. Stennes, 47, Minneapolis physician, died December 10th. He was born at Haynes, North Dakota, and studied at Concordia College at Moorhead, Minnesota, the University of North Dakota and Washington University in St. Louis, Missouri.

Dr. Stennes was a former chief of staff at Swedish Hospital in Minneapolis. He was a member of the Hennepin County Medical Society, Minnesota State Medical Association and American Medical Association.

He is survived by his wife, a son and a daughter.

DAVID KADESKY

Dr. David Kadesky, former St. Paul physician, died December 5th in San Francisco. Dr. Kadesky practiced in the Hamm building in St. Paul. He is survived by his wife.

JOHN E. POWER

Dr. John E. Power, 73, retired Duluth physician, died December 18th after a long illness. A native of London, Ontario, Dr. Power was a graduate of Queens University Medical School, Kingston, Ontario.

He was a past chief of staff of St. Mary's hospital, a fellow of the American College of Surgeons, a member of the St. Louis Medical Society and American Medical Association, and a life member of the Minnesota State Medical Association.

He is survived by his wife and three sons, one of whom is Dr. John E. Power, Jr. of Duluth.

AXEL S. N. NORAN

Dr. Axel Noran, 77, Edina pediatrician, died December 27th. He was born at Fergus Falls, Minnesota, and received his degree of medicine from Northwestern University at Chicago.

He was a member of the Hennepin County Medical Society and American Medical Association. Dr. Noran was a 50 Club member of the Minnesota State Medical Association.

He is survived by his son, Dr. Harold H. Noran of Edina.

RICHARD F. KLINE

Dr. Richard F. Kline, 40, St. Cloud physician, died December 24th. Born in Grand Rapids, Minnesota, he was a graduate of the University of Minnesota School of Medicine.

Dr. Kline was a member of the Stearns-Benton Medical Society, Minnesota State Medical Association, American Medical Association, American College of Physicians, Association of Minnesota Internists, Sertoma Club and Elks Club.

He is survived by his widow and four children.

EDWARD V. GOLTZ

Dr. Edward V. Goltz, 84, St. Paul physician, died December 9th, after a long illness. He was born at Winona, Minnesota, and obtained his medical education at Northwestern University Medical School.

Dr. Goltz was the first medical director of the St. Paul Red Cross regional blood program and a member of the Minnesota Academy of Medicine, Ramsey County Medical Society, American Medical Association, a fellow of the American College of Physicians and a 50 Club and Life member of the Minnesota Medical Association.

He is survived by his wife, one daughter and three sons, two of whom are Dr. Robert Goltz of Minneapolis and Dr. Neill Goltz of Fargo.

Of 748 patients with confirmed G.U. infections... 684 or 91.4% were treated successfully with Signemycin®

Note:
The efficacy of Signemycin was shown in a study of nongonococcal urethritis involving over 1600 patients.* A comparison of the cure rates of sixteen antibiotic and chemotherapeutic agents revealed that Signemycin had the highest incidence of successful response. One hundred and six patients were treated, of which 82 were followed, with cures in 70.

The Blue Shield

Excess Payments From Health Insurance

Should a patient be able to profit financially from a stay in a hospital or by receiving a doctor's services? This question is being raised with greater frequency since research studies indicate that 8 to 15 per cent of those who have prepayment insurance coverage of their hospital, medical, and surgical charges have one or more additional policies.

Because of this duplication of coverage, some commercial health insurance carriers are adding a "No Duplication" clause to many of their group contracts and to some of their direct pay contracts.

. . . If such a clause were included in contracts, it would mean that the Blue plans and any commercial insurance companies involved in covering these subscribers would pay benefits totaling up to the full amount billed for services but would not allow the subscriber, ill as he may be, to make money from prepaid insurance.

If this nonduplication clause were to be included in health care contracts, it would undoubtedly lead to a reduction in the rates charged for such coverage. The rate should fall because (1) duplicate administration would occur less frequently and (2) three or four companies would not pay their maximum on one operation. Look at an example. Blue Shield, Company A and Company B have coverage on you. You have your appendix removed. You collect for Blue Shield, and A, and B. Three groups therefore pay for removal of the same appendix. At the end of the year, the actuaries of all three organizations set up the cost of their policies based on how much usage they had experienced in the past year. Your appendectomy boosts all three firms' figures for the number of operations performed that year. This in turn increases the cost of the policy. What should happen is that the primary insurer (the one who insured the breadwinner) would pay its full fee for the appendectomy and then if there is a remaining unpaid bill, the other two companies divide the cost evenly. The patient gets his bill paid and the companies have fulfilled their obligation. The use of health insurance to pay for unemployment, maid service, or just plain profit will produce overpriced health insurance.

If the Blue plans and the commercial health insurance plans did adopt this nonduplication clause, they would be following a pattern already set in fire insurance and in automobile insurance coverage.

Prepayment of health insurance cost has become an integral part of our American way of life. We have a responsibility to our patients to see that quality health care is provided as reasonably as possible so that our patients would not have to allocate too large a portion of their income on expenditures for this care. These expenditures, of course, include premium payments for health insurance.

We are in an era of rapidly rising health costs, and therefore we must urge our patients to purchase full but not excessive coverage. This would mean, in effect, giving our wholehearted cooperation to all health insurance carriers as they make an effort to eliminate excess payments for health care in order to reduce the cost of their insurance. You and I, as members of the medical profession, know that three problems face us with greater frequency. These problems include (1) a sufficient number of hospital beds; (2) efficient utilization of these beds, and (3) the most efficient expenditure of funds for every phase of health care. It is up to us to see that our patients are able to live within a predictable budget for their health care cost. A nonduplication clause, providing coverage for no more than the full charges, is one way of preserving private medicine in this nation . . .

John T. Stage, M.D.
The Journal of the Florida Medical Association

"Million Dollar" Year

Blue Shield of Minnesota has completed its third successive "million dollar" growth year.

Blue Shield had revenues in 1964 which reached \$14.5 million, or more than \$1 million over the previous year. This is a dramatic gain since 1961 when premiums were about \$10.8 million.

With this financial growth, Blue Shield continued to return approximately 90¢ in benefits from every dollar in premiums collected from subscribers. At the same time, the Minnesota Plan maintained a reserve fund of nearly \$3 and ¾ million, which is the second highest level of reserves since Blue Shield began in 1947.

Blue Shield has already paid out more than \$115 million in benefits for Minnesota physicians since the plan began in 1947.

SIGNEMYCIN®

Side Effects: Glossitis and allergic reactions, as well as severe anaphylactoid reactions, have been reported as rare side effects. Should significant reaction or idiosyncrasy occur, discontinue medication and institute countermeasures. Use of tetracycline during the last trimester of pregnancy, neonatal period and early childhood may cause discoloration of developing teeth. Reduce usual oral dosage and consider serum level determinations in patients with impaired renal function to prevent possible liver toxicity due to excessive accumulation of antibiotic in the serum.

Precautions: Overgrowth of nonsusceptible organisms may occur. In such cases, discontinue medication and institute appropriate specific therapy as indicated by susceptibility testing. Aluminum hydroxide gel given with antibiotics has been shown to decrease their absorption and is contraindicated. The coloring agents used in Signemycin Syrup and Pediatric Drops may produce red discoloration of stools.

Triacetyloleandomycin, a constituent of Signemycin, administered to adults in daily oral doses of 1.0 Gm. (3 Gm. Signemycin) for periods of more than ten days may produce hepatic dysfunction and jaundice. In the rare patient who requires this high dosage level of Signemycin initially, liver function should be carefully followed and dosage should be reduced, as promptly as possible, to the usual recommended range of 1.0 to 2.0 Gm. per day. Therefore, Signemycin is recommended primarily for the treatment of acute or severe infections, with treatment restricted to a ten-day period. If clinical judgment dictates continuation of therapy beyond ten days, serial monitoring of the liver profile should be carried out, including BSP, transaminase, and cephalin flocculation tests. Changes observed in liver function were reversible following discontinuation of the drug.

Formulas: Capsules: 250 mg. Signemycin (167 mg. tetracycline HCl and 83 mg. oleandomycin as triacetyloleandomycin).

Capsules: 125 mg. Signemycin (83 mg. tetracycline HCl and 42 mg. oleandomycin as triacetyloleandomycin).

Syrup: 125 mg. Signemycin (tetracycline equivalent to 83 mg. tetracycline HCl and 42 mg. oleandomycin as triacetyloleandomycin) per 5 cc.

Pediatric Drops: 100 mg. Signemycin (tetracycline equivalent to 67 mg. tetracycline HCl and 33 mg. oleandomycin as triacetyloleandomycin) per cc.

More detailed professional information available on request.

Science for the world's well-being® Pfizer *Since 1849*

PFIZER LABORATORIES Division, Chas. Pfizer & Co., Inc. New York, New York 10017

®

Of 5,057 patients with confirmed infections of all body systems... 4,731 or 93.5% were treated successfully with Signemycin®

Note:

The high rate of response to Signemycin in these cases is noteworthy because the totals include many patients with difficult-to-treat infections, many whose infections had proved resistant to other agents, and many who had been treatment failures on other therapy.[1-87] In addition the following criteria were used for the cases cited: (1) only published results were used (2) results were confirmed by clinical and/or laboratory findings (3) patients were cured, not "improved" (4) dosage conformed with current recommendations in the United States (5) no other anti-infective agents were used concomitantly (6) no instance of prophylactic use was included in these tabulations.

Condition	No. of Patients	No. Responded To Signemycin
Ear, nose and throat infections	507	465
Respiratory infections	1,028	954
Gastrointestinal infections	425	387
Genitourinary infections	748	684
Skin and soft-tissue infections	1,088	1,036
Bone and joint infections	71	64
Deep-seated or generalized infections	257	251
Obstetrical & gynecological infections	341	320
Miscellaneous conditions	592	570
Totals	5,057	4,731 (93.5%)

consistently effective...often when others fail

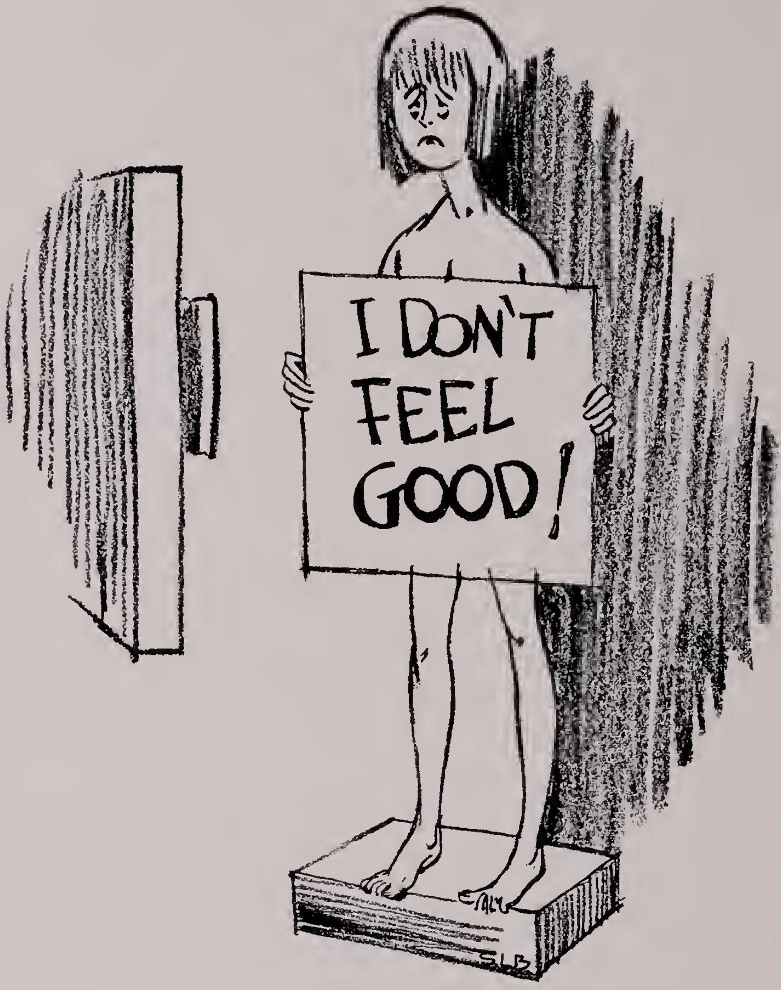
Better Service, Doctor?



Yes, Blue Shield wants to serve Minnesota doctors even better than it has. But we need your help.

When reporting claims, list symptoms for diagnostic laboratory and x-ray services ONLY. We do not need symptoms for any other service.

And, there must be a *direct* connection between those symptoms and the tests.

Payment for incomplete reports might be delayed . . . or rejected. Help us help you!

MINNESOTA'S LARGEST MEDICAL-SURGICAL PLAN

BLUE
SHIELD
OF MINNESOTA

2218 UNIVERSITY AVE. • ST. PAUL, MINNESOTA

Continued from Page 260

WANTED: full-time industrial physician for East Central Iowa industrial plant — excellent opportunity. General practitioner preferred, salary open. Immediate opening. Write: MINNESOTA MEDICINE — 299, 496 Lowry Medical Arts Building, St. Paul, 55102.

WANTED AT ONCE — A general practitioner for fine equipped office, 25 bed hospital, Eventide Home and Nursing Home. Call 427-3515 collect or write: Albert W. Steinle, Box 577 Mountain Lake, Minnesota.

USED CLINICAL SUPPLIES FOR SALE. Selling complete clinic — office equipment to X-ray. May be purchased as unit or by item. Contact: C. E. Overby, Madison, Minnesota.

WANTED general practitioner to join clinic close to Minneapolis, anytime between first of the year and the summer. State nationality and religion — Catholic preferred. Write: MINNESOTA MEDICINE — 297, 496 Lowry Medical Arts Building, St. Paul, 55102.

PHYSICIANS WANTED, OREGON COAST —pediatrician, urologist and general practitioner to join group of four internists, surgeon and two GPs. Well established with excellent facilities and reputation. Astoria Clinic, 812 Exchange Street, Astoria, Oregon 325-4111.

PRACTICE FOR SALE. General practitioner. Will practice for six months with prospective buyer to acquaint him with patients. All new equipment from BMR to X ray. See 20-30 patients daily. Reasonable and terms. Dr. A. H. Wolf, 3145 Hennepin Avenue South, Minneapolis, 55408.

EK-2 Burdick excellent condition, rolling stand. Not more than 200 recordings made. Asking $500. Will accept best offer. Owner in residency training. Call 724-7823 or Radiology Department, VA Hospital PA 9-2381.

WANTED general practitioner for St. Paul area. Would like partnership or association basis. Large one doctor office with large well-established practice. Write: Dr. C. M. Kelsey, 1530 West Larpenteur, St. Paul 55113.

MORGAN, MINNESOTA, Wants General Practitioner — Present Physician retiring after 33 years. Opportunity to take over well established practice. Progressive community in the best rural area of Southern Minnesota. Office space and equipment available. Call or write John Hageman, Pharmacist, Morgan, Minnesota. Telephone Morgan No. 96.

PEDIATRICIAN — to head pediatric department of expanding prepaid medical specialty group; Minneapolis-St. Paul; excellent beginning salary; opportunity for teaching and professional pursuits; liberal vacation and benefits. Alfred F. Anderegg, M.D., Medical Director, 2500 Como Avenue, St. Paul 8, Minnesota.

WANTED: General practitioner for Northern Minnesota town. An eight-room clinic located on main street equipped with X ray, etc. Previous practitioner left because of ill health after ten years profitable practice. Golf, hunting and fishing. No initial investment necessary. Write: MINNESOTA MEDICINE — 294, 496 Lowry Medical Arts Building, St. Paul, 55102.

BURNSVILLE MEDICAL CENTER — office space for one, two or group of physicians in Twin Cities fastest growing suburb — ideal for second office. Call Minneapolis 890-1434 or St. Paul 698-8618.

WANTED: General practitioner by established three-man group in own building, fully equipped. Southwestern Minnesota — county seat — population 3,500. New hospital — fine churches — good schools, public and parochial. Golf club — grass greens. Hunting and fishing. Starting salary with opportunity for partnership. No initial investment necessary. Write: MINNESOTA MEDICINE — 199; 496 Lowry Medical Arts Building, St. Paul 55102

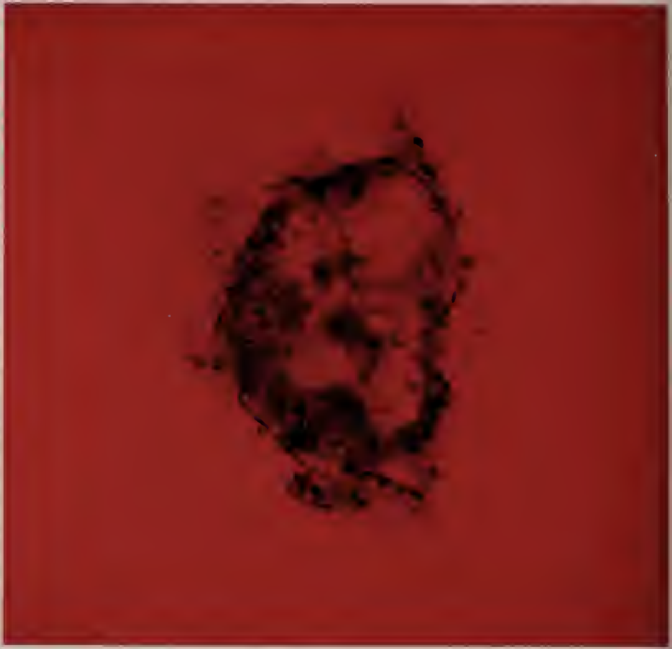
WONDERFUL OPPORTUNITY — Mankato, Minnesota — for a specialist in ENT, OB-GYN and urology in independent practice. Referral practice assured. Office space available. City is 35,000 with trade area of 160,000. Two excellent hospitals with open staff of 60 men, 40 of whom are specialists. Mankato State College enrollment over 8,000 with excellent nursing school. Extremely well-balanced, diversified economy. Write: MINNESOTA MEDICINE — 295, 496 Lowry Medical Arts Building, St. Paul, 55102.

The difference is that a statesman thinks he belongs to the State, and a politician thinks the State belongs to him.

Big men became big by doing what they didn't want to do when they didn't want to do it. — Insurance Salesman

kills Haemophilus influenzae in respiratory infections

Electron micrograph of normal H. influenzae *organism.*



Electron micrograph of H. influenzae *after a 2-hour exposure to a therapeutic (8γ/ml.) dose of PENBRITIN (ampicillin).*

New broad-spectrum penicillin:

- most active antibiotic against *Haemophilus influenzae*[1-3]—a major pathogen in chronic bronchitis and respiratory infections in children
- demonstrated clinical efficacy and safety in chronic bronchitis[4-10]
- more effective than tetracycline in reducing sputum in chronic bronchitis[5]

Usual Adult Dosage: 250 mg. every six hours. *Usual Dosage for Children*—(under 13 years, whose weight will not result in a dosage higher than that recommended for adults) 100 mg./Kg./day in divided doses every six or eight hours for moderately severe infections; 200 mg./Kg./day in divided doses every six hours for severe infections.

Contraindications: (1) Hypersensitivity to penicillin. (2) Infections by penicillinase-producing staphylococci or other penicillinase-producing organisms.

Side Effects: Mild effects, such as skin rashes, diarrhea, nausea and vomiting, have occasionally appeared.

Precautions: As with other antibiotics, precautions should be taken against gastrointestinal superinfection. To date, safety for use in pregnancy has not been established.

Supplied: No. 606—Each capsule contains 250 mg. of ampicillin. Bottles of 16 and 100.

Hygroton®
brand of
chlorthalidone
the long-acting diuretic

Indications
Many types of edema involving retention of salt and water.
Contraindications
Hypersensitivity, and most cases of severe renal or hepatic disease.
Precautions
Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Side Effects
Constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, leukopenia, muscle cramps, nausea, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.
Average Dosage
One tablet (100 mg.) daily with breakfast.
Availability
Tablets of 100 mg. in bottles of 100 and 1000.
For full details, see the complete prescribing information.

Geigy Pharmaceuticals
Division of
Geigy Chemical Corporation
Ardsley, New York

How does Hygroton®
brand of
chlorthalidone
stack up against other diuretics?

Not very high. In terms of one week's therapy, that is. The usual dosage is just one tablet per day. Very often, the dosage is even lower. So a week's therapy doesn't amount to much.

That's why it's nice to work with Hygroton®, brand of chlorthalidone. You have fewer tablets to prescribe. Your patients have fewer tablets to take. And fewer to pay for.

For sheer diuretic effectiveness, choose Hygroton®, brand of chlorthalidone. It generally promotes more natruresis per tablet than the thiazides. We'll stack it up against any diuretic.

Geigy

in maintenance therapy... a working analgesic for the active arthritic

ARTHRALGEN®

Each tablet contains:

Salicylamide	250 mg.
Acetaminophen	250 mg.
Ascorbic acid (Vitamin C)	25 mg.

a working analgesic for the active arthritic

—rapidly relieves early morning stiffness and arthritic pain. It promises a quicker response in most patients because its analgesic ingredients need no metabolic conversion before they act. As a combination of two prominent analgesic drugs, Arthralgen can often establish smoother, more complete pain relief because it synergistically produces more efficient analgesia on lower dosage levels of each.

two proven pain relievers

Arthralgen combines two better-tolerated, time-tested analgesics, acetaminophen and salicylamide, into a pharmacologically sound and therapeutically effective formulation. As Arthralgen, it penetrates tissues promptly and relieves pain rapidly with less likelihood of gastric irritation than aspirin.

sodium-free

Arthralgen contains no sodium. Therefore, it is often a safer and more suitable analgesic for use in the long-term treatments of arthritic patients who have other conditions which require sodium restriction.[1]

ARTHRALGEN®-PR (Arthralgen with prednisone)

Each tablet contains:

Salicylamide	250 mg.
Acetaminophen	250 mg.
Ascorbic acid (Vitamin C)	25 mg.
Prednisone	1 mg.

To help provide dosage flexibility in patients who require steroids, the basic Arthralgen formula is also available combined with prednisone as Arthralgen-PR. Prednisone is favored as the more advantageous steroid for use in Arthralgen-PR because it shows less tendency toward sodium retention, potassium excretion, and steroid-induced hypertension than that which often accompanies the use of cortisone and ACTH.[2]

A. H. ROBINS COMPANY, INCORPORATED/RICHMOND, VIRGINIA

BRIEF SUMMARY

Arthralgen and Arthralgen-PR are indicated in the management of rheumatoid arthritis, acute gouty arthritis, rheumatoid spondylitis, osteoarthritis, bursitis, fibrositis, and neuritis. Arthralgen may be used for analgesia in colds, flu, and various myalgias.

DOSAGE: One or two tablets four times a day. After remission of symptoms dosage should be reduced to the minimum maintenance level.

SIDE EFFECTS: Nausea, GI upset, or mild salicylism may rarely occur. Symptoms of hypercorticoidism dictate reduction of dosage of Arthralgen-PR.

PRECAUTION: Reduction in dosage of Arthralgen-PR given over a long period should be gradual, never abrupt.

CONTRAINDICATIONS: Hypersensitivity to any ingredient.

As with any drug containing prednisone, Arthralgen-PR is contraindicated, or should be administered only with care, to patients with peptic ulcer, tuberculosis, nephritis, diabetes mellitus, acute psychoses, Cushing's syndrome (or Cushing's disease), overwhelming spreading (systemic) infection, or predisposition to thrombophlebitis.

Arthralgen-PR is generally contraindicated in patients with uremia and viral infections, including poliomyelitis, vaccinia, ocular herpes simplex, and fungus infections of the eye. It is also contraindicated in patients with chicken pox or susceptible persons exposed to it.

SUPPLY: Arthralgen (white, scored) and Arthralgen-PR (yellow, scored) tablets are available in bottles of 100 and 500.

epilepsy can undermine self-reliance

"A therapeutic 'bull's-eye' may be scored with DILANTIN [diphenylhydantoin] even for a person with long-standing convulsions previously unrelieved by phenobarbital."* Such efficacy can make a substantial contribution to your epileptic patient's rehabilitation . . . improve his prospects for employment . . . foster greater self-reliance.

Indications: Grand mal epilepsy and certain other convulsive states. **Precautions:** Toxic effects are infrequent: allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Eruptions then usually subside. Though mild and rarely an indication for stopping dosage, gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered, especially in children, adolescents, and young adults. During initial treatment, minor side effects may include gastric distress, nausea, weight loss, transient nervousness, sleeplessness, and a feeling of unsteadiness. All usually subside with continued use. Megaloblastic anemia, aplastic anemia, leukopenia, granulocytopenia and pancytopenia have been reported. Nystagmus may develop. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. Adequate examination of the blood is advisable. DILANTIN (diphenylhydantoin sodium) is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm.

FOR YOUR ELDERLY ARTHRITIC PATIENTS...

an effective **GERIATRIC** antiarthritic with

REASSURING SAFETY FACTORS

Effectiveness, dependability and reassuring Safety Factors make PABALATE-SF a logical choice for antiarthritic therapy in elderly patients—even when osteoporosis, hypertension, edema, peptic ulcer, cardiac damage, latent chronic infection and other common geriatric conditions are present. The potassium salts of PABALATE-SF cannot contribute to sodium retention...the enteric coating assures gastric tolerance...and clinical experience shows that this preparation does not precipitate the serious reactions often associated with corticosteroids or pyrazolone derivatives.

Side Effects: Occasionally, mild salicylism may occur, but it responds readily to adjustment of dosage. Precaution: In the presence of severe renal impairment, care should be taken to avoid accumulation of salicylate and PABA. Contraindicated: An hypersensitivity to any component.

Also available: PABALATE—when sodium salts are permissible. PABALATE-HC—Pabalate-SF with hydrocortisone.

Pabalate-SF

A. H. ROBINS CO., INC., RICHMOND 20, VIRGINIA

In each persian-rose enteric-coated tablet: potassium salicylate 0.3 Gm., potassium aminobenzoate 0.3 Gm., ascorbic acid 50.0 mg.

—the new, convenient way to prescribe
PABALATE-SODIUM FREE

GENERAL INFORMATION

Authors

Manuscripts for consideration in Minnesota Medicine should be addressed to Office of Publication, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Papers should be typed double spaced on white paper with a wide margin. The first page should list the title, the name of the author (or authors), degree, and any institutional or other credits. Pages should be numbered consecutively. Tables should be typed and numbered and should have a brief descriptive caption.

Bibliographical references should be limited to twelve and should be typed in conformity to the method used by the Index Medicus. They should be numbered consecutively in the order in which they first appear in the text. Book references should give the name of the author, title, edition number, publisher, and the year.

Illustrations (photographs, tables, and graphs) should be submitted on separate sheets of paper and not combined in the text. Instructions for combining photographs are acceptable.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association of any of its constituents.

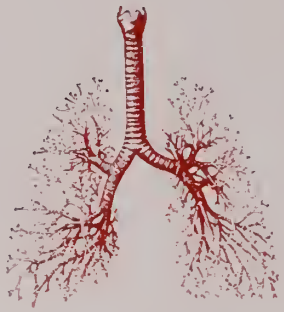
Fewer bacterial resistance problems when you treat infections



PENBRITIN®

Brand of Ampicillin

kills bacteria...does not just suppress them!

With PENBRITIN (ampicillin) the emergence of resistant strains of organisms is *slow* rather than rapid as with other antibiotics.[1,2] Tetracycline-resistant hemolytic streptococci and pneumococci have been reported[3-6]—but this has not been a problem with PENBRITIN (ampicillin). According to an editorial in *Lancet*,[2] PENBRITIN (ampicillin) could be particularly valuable in *killing* coliforms and *Proteus*, which may otherwise quickly become resistant during treatment. Recently, several *Shigella* strains, resistant to tetracycline, chloramphenicol, and other antibiotics, were found to be susceptible to ampicillin.[7]

Dosage: Adults—250 mg. every six hours in respiratory infections; 500 mg. every six hours in urinary and gastrointestinal infections (higher doses may be needed in severe infections). Children—(under 13 years, whose weight will not result in a dosage higher than that recommended for adults) 100 mg./Kg./day in divided doses every six or eight hours; 200 mg./Kg./day in divided doses every six hours for severe infections.

Contraindications: (1) Hypersensitivity to penicillin. (2) Infections by penicillinase-producing staphylococci and other penicillinase-producing organisms. *Aerobacter aerogenes, Pseudomonas pyocyanea,* and *Proteus morganii* are resistant to PENBRITIN (ampicillin).

Side Effects: Mild effects, such as skin rashes, diarrhea, nausea and vomiting have occasionally appeared.

Precautions: As with other antibiotics, precautions should be taken against gastrointestinal superinfection. To date, safety for use in pregnancy has not been established.

Supplied: No. 606—Each capsule contains 250 mg. of ampicillin. Bottles of 16 and 100.

President's Letter

In view of the widespread discussion about methods of medical care for the American people, it seems pertinent to review the policies of the American Medical Association on this subject. The American Medical Association has always taken the position that no one should lack medical care because of inability to pay for it, and traditionally physicians have supported this principle and have annually provided free care which is estimated to amount to several hundred million dollars. The American Medical Association has repeatedly opposed public care for those who are able to pay their medical bills and for whom no governmental responsibility is evident. Such responsibility has been recognized by organized medicine, but always for a specific need.

From an early date the American Medical Association has supported a Public Health Service. The Armed Servicemen, together with their dependents, retired personnel and those disabled in service have been cared for at government expense with the cooperation of the American Medical Association. Most of this care is rendered by physicians who are employed by the government or are in the Armed Services, but some of it is provided by contract with private physicians.

The American Medical Association has steadfastly insisted on freedom for the patient to choose the physician or the method of health care of his choice, and it has been concerned that in any plan the physician have freedom to provide the best possible care.

When a financial need exists, the American Medical Association has asked that the responsibility be discharged at a level as close to the patient as is possible, and it has opposed direct use of federal funds on the assumption that at a national level of administration the physician's control to ensure the best medical care may be lessened. The association has endorsed the principle that when federal aid is necessary, it should supplement state or local funds and be administered through state or local governmental agencies.

The American Medical Association supports the principles of voluntary health insurance and the prepaid Blue Cross and Blue Shield plans, including coverage for catastrophic illness through major medical insurance. Direct federal subsidization of prepayment plans and health-insurance companies has been considered undesirable. This does not, of course, include the purchase of such care for federal employees by the government as an employer. A number of states have purchased insurance and service plans for the medically indigent with the full approval of the organized medical societies and the American Medical Association.

In December, 1964, at Miami the House of Delegates clarified the American Medical Association's position by adopting the following resolution: "The House of Delegates urges the component associations of the American Medical Association to stimulate the state and local governments to seek the fullest implementation of existing mechanisms including the voluntary health insurance principles to the end that everyone in need, regardless of age, is assured that necessary health care will be available."

With the foregoing principles outlined as a background, it will be apparent why the

This is the kind of breakfast used in the Griffith and Black study reported here.

Consider V-Cillin K, the acid-stable penicillin that is less affected by gastric acids than is oral penicillin G. In fact, comparative data show that V-Cillin K given with meals produces blood levels *twice* as high with just *half* the dose. Such pharmacologic characteristics provide your patients consistently dependable therapy. In addition, significant economy is achieved, since three to four times as much oral penicillin G is required to assure equivalent antibacterial activity.[1]

[1] Griffith, R.S., and Black, H.R.: Current Ther. Res., *6:*253, 1964.

Indications: V-Cillin K is an antibiotic useful in the treatment of streptococcus, pneumococcus, and gonococcus infections and infections caused by sensitive strains of staphylococci. *Contraindications and Precautions:* Although sensitivity reactions are much less common after oral than after parenteral administration, V-Cillin K should not be administered to patients with a history of allergy to penicillin. As with any antibiotic, observation for overgrowth of nonsusceptible organisms during treatment is important. *Usual Dosage Range:* 125 mg. (200,000 units) three times a day to 250 mg. every four hours. *Supplied:* Tablets V-Cillin K, 125 or 250 mg., and V-Cillin K, Pediatric, 125 mg. per 5-cc. teaspoonful, in 40, 80, and 150-cc.-size packages.

Premalignant Lesions of the Colon and Rectum[*]

A perplexing problem influencing the practice of all clinical physicians.

ROBERT TURELL, M.D.**
ALBERT S. LYONS, M.D.**
New York, New York

A CONTROVERSY is in progress regarding the "premalignant" status of a number of polypoid and inflammatory lesions of the anorectocolonic tube. These include (1) adenomas; (2) chronic ulcerative colitis; (3) venereal diseases such as venereal lymphogranuloma, and Donovanosis,*** and (4) fistulous and sinous tracts. Not only is there dissension in interpretation of the basic facts; there is not even agreement on the precise definition of the words "premalignant and precancerous." To some clinicians these terms mean the inevitable transformation from a benign to a malignant process. To others, they suggest only a greater chance of developing cancer. Agreement on terms of polyp and the various types of adenomas is most essential, and the reader is referred to our most recent paper on this subject.[1]

In presenting opposing views we have been guided by Charcot's long remembered saying, "Disease is very old and nothing about it has changed. It is we who change as we learn to recognize what was formerly imperceptible." What is "irrefutable evidence" today may later be proved erroneous. The great issue here is not agreement but debate which may ultimately lead to a better understanding of the problem.

Adenoma

If all adenomas do eventually become invasive cancer, then all adenomas should be removed before they become cancer. If some but not all adenomas do become cancer, then there should be ways of distinguishing which are "premalignant" and which are benign. The morbidity and mortality of the various methods of surgical removal of adenomas as compared with the chances of transformation to cancer must be given consideration.

Many pathologists and clinicians believe that most colonic adenomas eventually become cancer. The evidence consists of: (1) the allegedly similar distribution of cancer and adenomas; (2) the younger age incidence of adenoma and the older age occurrence of cancer; (3) the high incidence of adenomas in patients with cancer of the colon; (4) the frequency of colonic cancer among patients with colonic familial polyposis, and (5) the demonstration in individual specimens of a transition from adenoma to adenocarcinoma.

Similar Distribution

Authors who favor the direct relationship concept claim that adenomas and cancer occur with similar frequency in the same segments of the bowel. However, even the actual incidence of adenomas is not clearly established. Reported frequency has varied from 1.7[2] per cent to 69 per cent.[3] Wide differences exist in the interpretation of mucosal excrescences and in the methods of evaluating different populations.[4] With such conflicting data, considerable confusion is bound to result from trying to correlate incidence and distribution.

In 1939, Klemperer[5] reviewed the literature on adenomas and reported that the autopsy findings of Reichel and Staemmler in 1924 were *not* supported by more recent reports. He noted that whereas only 44 per cent of adenomas occurred in the rectum and sigmoid, 75 per cent of colonic cancers occurred in these same locations; further he noted that in patients beyond 40, adenomas are too frequent to allow statistical age comparisons with the incidence of cancer. He therefore concluded that there was no evidence for a direct relationship between adenomas and cancer. On the other hand, Swinton and Haug[6] came to the contrary conclusion on the basis of 1,843 autopsies, in which 73.5 per cent of cancers and 52.2 per cent of adenomas were found in the distal colon. Thus, with data similar to Klemperer's their interpretation was diametrically opposite.

Bockus et al.[7] and Koppel et al.[8] reported that among two groups of people, one with and the other without adenomas, both developed the same numbers of cancers. Spratt et al.[9] used statistical analyses and discovered that both adenomas and cancer occurred with greatest frequency in the cecum; but in the rectum and sigmoid, cancers were considerably more frequent than adenomas. This would mean that even if all adenomas were to become malignant, this transformation could *not* account for all the cancers found. Some cancers would have had to arise *de novo,** without first being adenomas.[10]

Age Succession

Buie and Brust[11] stated that there is a nine-year difference in the average age of patients with adenomas and cancer, and their inference was that these years represented the time needed for the adenomas to become cancer. However, Andren[12] has reported a higher incidence of adenomas in the first decade than in either the second or third, and Bockus et al.[7] and Enterline[13] noted that the average age of patients with adenomas resembled the average age of patients with cancer.

Spratt et al.[9] indicated that after the age of 50 cancers were found in polyp-containing and polyp-empty colons with the same relative frequency, but in younger patients (30 to 49 years old) there was a definite increase of cancers among those with adenomas.

Incidence of Adenomas in Patients With Cancer

Dukes,[14] and Goligher[15] found that a high proportion of colons with cancer also had adenomas. A study by Rider et al.[16] presented strong evidence that patients with multiple adenomas are twice as likely to develop cancer as those with solitary adenomas. However, these authors concluded that their findings did *not* corroborate a direct relationship between adenoma and cancer, but instead indicated that the mucosa of people with adenomas has an increased tendency to form more neoplasms, cancers as well as adenomas.[17]

Cole et al.[18] studied the records of 87 patients with invasive cancer of the colon who survived operation and found that those with adenomas had a lower incidence of involved lymph nodes and a higher survival rate than those without associated adenomas. Recalling that Valdes-Dapena and Beckfield[19] had previously described the earliest change in the formation of an adenoma to be thickening of the submucosa, Cole and his co-workers suggested that this thickening might act as a barrier to the development and spread of a cancer. Contrarily, the study by Grosberg and Galambos[20] did not reflect an enhanced resistance to neoplasia, but rather an increased "susceptibility" to cancer in colons with adenomas.

---

Incidence of Cancer in Patients With Multiple Polyposis

Congenital Familial Polyposis

Dukes[20,21] reported that among 700 members of 57 families, 251 developed multiple polyposis. Invasive cancer developed in 114 of the first 156 studied.

However, what would seem to be an obvious close relationship to malignancy is not so clear-cut on more detailed study. For example, numerous authors have emphasized that the patients with familial polyposis may have an altered hereditary response of their colonic mucosa and therefore the polyps themselves may not be the origin of the cancers. Spratt et al.[9] showed that the distribution of colonic cancers in patients with familial polyposis was exactly the same as in colons without any adenomas. These observations do *not* deny the occurrence of cancer in people with congenital polyposis but instead indicate that the occurrence of cancer does *not* follow the distribution of the adenomas!

Assuming two types, one familial and the other nonfamilial, the comparisons made between solitary and familial cases have not revealed differences in size, number, or distribution of the polyps and tumors, or any differences in the age of onset, symptoms, or course of the disease. Individual patients with multiple polyposis appear to develop carcinoma after the same average period (about 15 years). Also, the average age of death is the same for both solitary and familial forms. It may be that some of the solitary cases are merely the first manifestation of a gene mutation, so that although these patients have not inherited polyposis from their forbears, they may transmit the disease to their offspring. Thus, the solitary and the familial types may be regarded as examples of the same disease.

Congenital polyposis may be associated with other abnormal growths in the body, such as fibromas, lipomas, fibrolipomas, epidermoid cysts, leiomyomas, dermoids, desmoids, osteomas, bony exostoses, and fibrosarcomas. The finding of these lesions should suggest the possible presence also of familial polyposis.

The Peutz-Jeghers Syndrome

In this syndrome, the polyps are predominantly located in the jejunum but may occur anywhere in the entire gastrointestinal tract. Usually, but not always,[23,24] mucocutaneous melanin pigmentation on the lips and gums is associated. On occasion, the pigmentation involves the palms and soles and their appendages. This syndrome is believed to be familial and hereditary, as a simple Mendelian dominant (gene), although isolated (sporadic) cases have also been reported

Until a few years ago, there existed considerable confusion in interpretation of pathologic data. The disease is now considered a specific pathologic entity with definite histologic features that are distinguishable from the pathologic patterns of other polypoid lesions of the alimentary tract.[25-28] Most workers[25,27] insist that the intestinal lesions are hamartomas.* Burdick et al.[24] have questioned the hamartomatous nature of this lesion; they feel that the presence of more than one major cell type cannot be considered proof of their hamartomatous nature.

Except for a rare dissent,[28] there is virtually unanimous agreement in the recent literature on the total absence of any cancer potential in the Peutz-Jeghers polyps.

The melanin pigmentation is considered one of the main symptoms of this syndrome. However, Turell et al.[23] have reported three cases of circumoral pigmentation without clinically detectable polyposis anywhere in the alimentary tract, and two that were associated with true adenomas in the rectosigmoid. Burdick et al. had also observed pigmentation without polyps in their extended study of one large family. It should also be remembered that melanin pigmentation may be physiologic in some persons, may occur in the familial form of polyostotic fibrous dysplasia (Albright's disease), or may follow the administration of certain drugs such as quinacrine hydrochloride.[29]

---

*See Test Your Word Score Page 359.

Juvenile Polyp (Also known as congenital cystic polyp; retention polyp, and juvenile adenoma)

Gelb et al.[30] reported 19 polyps in children (two to 17 years of age). Three were typical adenomas; eight were juvenile polyps (with granulation tissue replacing mucosa and stroma, and with neutrophilic and eosinophilic infiltration); five were purely inflammatory, and three showed features of both adenoma and juvenile polyp. The juvenile polyps were considered adenomatous polyps with the inflammatory changes that follow surface erosion.

Roth and Helwig[31] have suggested that the juvenile polyp may actually be formed as a result of the cycle of ulceration and inflammation of the intestinal mucous membrane.

Whatever the pathogenesis of juvenile polyps may be, their insignificance as precursors of malignancy can be judged by the fact that not a single proved case of cancer has been found to arise in a juvenile polyp in a combined series of over 500 cases gleaned from the literature. Ackerman[32] has also stated that this type of polyp may not be a true neoplasm.

Histologic Evidence for Malignant Transformation

Interpretation of the available data is not simple. Not all pathologists agree on the precise criteria of malignancy in adenomas,[33,34] and the evidence for malignant change in adenomas is inconclusive.

Fractional Biopsies

The ultimate discovery of carcinoma after repeated benign fractional biopsies only emphasizes the limitations of fractional biopsy, rather than any transformation by the polyp. Furthermore, Colvert and Brown[35] have shown that in patients who refused to have their adenomas removed, the later incidence of cancer was essentially the same as in another group who did have their polyps removed. Thus the adenomas were benign or malignant at their origin and did not change into cancers.[36]

Transition from Benign to Malignant

Concerning the histologic finding of transition from adenoma to carcinoma in the same specimen, as originally championed by the German pathologists, the method of classification of the stages of atypism has been and often still is highly arbitrary.[37] Kaufmann[37] and Tonnesen[37] were among the first to criticize the interpretations. Yet Helwig[38] and others have continued to claim that there is a gradual transition from benign adenoma, through the stages of localized anaplasia, to clear (though low-grade) malignancy. Buie and Brust[11] have stated that they have found no evidence of higher grade of malignancy developing from an adenoma. Lane and Lev[39] have concluded, however, that most colonic cancers arise from adenomatous epithelium.

Most contemporary pathologists do not describe transitions through the stages of atypism to carcinoma. Some have described areas of frank invasive cancer in otherwise benign-appearing adenomas. Swinton and Warren[40] and others[38,41,42] reproduced photomicrographs of lesions considered to represent the transitions. Enterline[13] found a few remnants of what he interpreted to be the original adenoma, but he also conceded that others might consider the remnants to be highly differentiated adenocarcinoma and not adenoma.

Contrarily, after reviewing representative sections from 298 polypoid cancers, Ackerman[9] found no vestiges of a benign predecessor and agreed[33] with Castleman[43,44] that adenomas have a negligent malignant potential. He further argued that the current rate of small, infiltrating cancers arising from nonadenomatous mucosa can be shown statistically to be sufficient to account for all cancers of the colon.

There is considerable confusion on what is invasive cancer (in spite of agreement among most recent authors that local removal is entirely adequate for noninvasive cancer). Different interpretations of identical data can lead to completely different conclusions, as demonstrated by Castleman and Krickstein.[43] (The newer sophisticated studies reported elsewhere[1] may be of real help in this regard.)

It is of interest to note that Earle, as early as 1911, had written, "Non-malignant tumors are in fact less liable to originate malignant disease than are the normal morphological elements of the body itself."[45] Pennington in 1923 also believed that there was no evidence that a benign adenoma later becomes malignant.[45]

Recommended Procedure

No matter what the malignant potential of adenomas may be, we believe that all symptomatic adenomas should be extirpated. Removal is necessary in order to obtain a total biopsy, the only means of determining unequivocally the presence or absence of invasive cancer. There are few valid exceptions to this requirement. Particularly the short pedicled or sessile lesions should be removed, because they can be mimicked by cancer.

Poor Risk Patients

On the other hand, the asymptomatic small adenoma with a long pedicle, discovered on X-ray studies, in a poor risk patient may *not* require extirpation. However, even here it must be realized that malignancy may be present in the stalk.[36] In spite of the current belief[44,46] that metastases from cancers on a pedicle are negligible, the only way to determine the character of an adenoma is to remove it for histologic examination. Nevertheless, the pedunculate, smooth-contoured lesion beyond the reach of the sigmoidoscope in a patient who is a subnormal risk is sometimes better left alone.

Location of the Adenoma

Various aids are available at laparotomy to find adenomas: palpation of the gut, transillumination coloscopy through small incisions with and without insufflation, and extended colotomy incisions.[47] Actual palpation of the exposed polypoid lesion for the presence of induration is a surprisingly reliable indication of invasive malignancy. Frozen section examination of colon polyps unfortunately is often not helpful.

Removal of the Polyp

Polypectomy through colotomy incisions apparently is adequate for adenomas with long, true pedicles. Welch[48] and Castleman[43] have suggested that traction by the surgeon may give a false impression of the presence of a pedicle. However, follow-up study by us and by others indicates that a conservative operation is sufficient for the treatment of the mucosal lesion that is liftable (and therefore not fixed) from the underlying submucosal structures.

Contrarily, when any segment of the stalk, regardless of its length, is invaded by cancer, a segmental intestinal resection at the very least is needed, in our judgment. Conflicting opinions have been reported by McLanahan et al.,[49] Turnbull,[50] Dukes and Lockhard-Mummery.[22]

Subtotal colectomy and ileoproctostomy is still the most favored operation for the treatment of diffusely distributed multiple sessile or short-pedicled adenomas, as well as for congenital familial polyposis. Regression and spontaneous disappearance of the remaining rectal adenomas have been reported in isolated instances.[51,52]

Villous Adenoma

Villous adenoma has been assumed to originate in cells of the surface mucous membrane,[36] whereas adenoma is said to arise from the cells lining the intestinal mucous glands;[21] but Cole has suggested that both types may begin in the surface cells.[52a]

Combinations of villous and smooth adenomas in the same lesion and separately in the same colon have been seen frequently. We have encountered villous adenomas on pedicles and even on long stalks. Neither cell atypism nor mitoses are indicative of clinical malignancy. Furthermore, the size of the adenoma bears no relationship to the occurrence of cancer. We have observed invasive cancer in lesions smaller than 1 cm. in diameter and extremely large lesions without cancer.[36]

Precursor of Cancer

General opinion favors the belief that villous adenomas are often precursors of cancer.[46,53] Yet, except for the higher incidence of unequivocal cancer observed at the time of the initial examination, as compared with smooth adenomas, clear-cut evidence is not available that villous adenomas are more apt to undergo malignant degeneration.[21]

It is not determinable whether villous adenoma with invasive cancer was originally noncancerous. The often seen large villous adenoma of long duration which remains benign lends support to the concept that the coexistence of invasive cancer with villous adenoma may be guilt by association and not necessarily guilt by transformation. While the discovery of invasive cancer in a villous adenoma might be in keeping with the belief that villous adenomas may be subject to malignant change, a painstaking search of the literature has so far disclosed only one author[54] who himself has vaguely (certainly contestably) observed a benign villous adenoma undergo malignant transformation (actual invasive cancer) during his period of observation. In this instance, the report stated that a villous adenoma had been removed "which was reported by the pathologist to be a benign tumor. Four months later there was a recurrence which proved to be invasive carcinoma." The author added, however, that he was "willing to admit that the original diagnosis may have been in error."

Identification of Malignancy

The key to the dilemma, as in the problem with smooth adenomas, is in the criteria for malignancy. Interestingly, until about a decade ago, pathologists seldom reported noninvasive malignancy in villous adenomas. Recently more and more descriptions differentiate between noninvasive and invasive cancer.

The simultaneous occurrence of benign villous adenomas in one area of the colon and invasive cancer at another site in the colon is not uncommon. The character of the two lesions can often be distinguished roentgenologically. The radiologic features of villous adenoma have been well described by Wolf.[55] Clinically, with the adenoma accessible to palpation, induration is a strong indication that invasive cancer is present in the adenoma.

General opinion also subscribes to the belief that recurrence following local removal is a characteristic of villous adenoma. In our experience, and from the observations of others,[56,57] the rate of recurrence of smooth and villous adenomas is virtually the same. Furthermore, the recurrences have continued to be benign, following the removal of a totally benign villous adenoma.

On the other hand, it is also true that an invasive cancer may lurk in the depths of a villous adenoma, to be discovered only when the adenoma has been removed or after repeated extirpations.

How is the villous adenoma best treated? The methods advocated depend on the attitudes toward the cancer potential, and range from the radical to the conservative forms of surgical procedures.

Treatment

The conservative methods include local excision,[53,58] the Rehn-Delorme operation,[59] and electrocoagulation. The opposition to electrocoagulation is based on the concept that constriction of the rectum[54] may result and that multiple applications of electric energy to a tumor may lead to a "violently active malignant growth surge."[60] We have not been able to confirm this belief, after the use of electrothermic, amputative procedures, with either the snare or double loops resector. The "growth surge" is not due to the electrothermia but rather to an infiltrating cancer that was unrecognized at the initial treatment.

Resection of the segment of bowel containing a villous adenoma is considered good treatment. Whenever possible any site in the colon and rectum above the lower few inches can be radically excised as for cancer. Technically, even a large benign rectal villous adenoma can be totally extirpated with retention of the rectum.[61,62] However, an abdominoperineal resection of the rectum for a benign villous adenoma, as recommended by some,[63-65] is too high a price to pay. An unnecessary extensive resection when intestinal continuity can be restored is permissible, but the imposition of a permanent colostomy for a benign lesion is not warranted. The more radical operation can be performed if the histologic examination of the specimen removed by conservative procedures reveals invasive cancer. Some time may be lost, but many anal sphincters may thus be saved. Liechty and Raterman,[57] Dreese,[56] and Hightower[65a] hold similar views.

In addition, we have treated villous adenomas with noninvasive focal cancer by conservative procedures without recurrence when the surgical risk was high or when loss of the rectum would have been otherwise necessary. Hightower[65a] has also treated "villous adenoma with malignant foci" (the equivalent of noninvasive cancer) by a conservative method.

Of course, when invasive cancer coexists with villous adenoma, radical surgical operations, adhering to cancer principles, are mandatory.

In sum, meager evidence exists for the transformation of the smooth, lobulated, benign adenoma into invasive, metastasizing cancer.

On the other hand, the opinions of most authorities subscribe to a definite cancer potential of the villous adenoma. On the basis of our own observations, we consider the villous adenoma dangerous because it may contain an invasive cancer, but not because it is necessarily of itself a precursor of malignancy.

Fractional biopsy should be abandoned in favor of total biopsy, whenever possible. Resection for histologic verification of all symptomatic polypoid lesions (villous or smooth) is advisable, regardless of anatomic location.

Ulcerative Colitis

The first instance of cancer found in ulcerative colitis was reported by Yeomans.[66] Since then many papers[67-70] on the subject have appeared.

Incidence of Malignancy

In general, it is fair to state that the overwhelming consensus considers ulcerative colitis a dangerous precursor to cancer.[71-77] The incidence in ulcerative colitis has been variously estimated from 0 to 33 per cent.[78-80] Reports of cancer in children with colitis have also appeared.[81,82] Malignancies in ulcerative colitis arise at an earlier age — in the fourth versus the sixth decade. Cancer has occurred in even very small rectal stumps.[83] The time interval between the known onset of the inflammatory process and cancer has been variously estimated as from five to 12 years.[84,85] Aylett, a strong advocate of ileorectal anastomosis to diseased bowel, has nevertheless been reluctant to perform this procedure in long-standing ulcerative colitis, as rectal cancers have occurred in his patients often enough to be striking.[86]

On the other hand, a small but authoritative body of opinion[87-89] still holds that the association of ulcerative colitis and cancer is coincidental. They believe that in many cases the cause of the cancer is an undetected familial polyposis. The polypoid lesions are either hidden or destroyed by the superimposed inflammation. The reported statistics are regarded as deceiving because they are selected, not random, and stem from either surgical specimens or necropsies, making them highly selective and weighted heavily with severe disease. They also call attention to the not too well known fact that infrequently ulcerative colitis occurs after the onset of the cancer. The role of adenomas is no clearer in ulcerative colitis than in normal colons.

Whatever the ultimate truth may be, the important consideration today is whether the risk of cancer is great enough to require removal of the colon and rectum in any patient with long-standing ulcerative colitis (over 10 years),[70,85] regardless of symptomatology. On the basis of present knowledge, we would say, "No!"

In the first place, the highest incidence of malignancy is in the bowel that is healed, defunctionalized, or in a quiescent state.[80,90,91] This fact alone would preclude total colectomy as a practicable method of preventing cancer. Secondly, despite the numerous series and individual reports of the coexistence of colitis and cancer — strong evidence in favor of a relationship — we believe that the real incidence of malignancy in ulcerative colitis is much smaller than is suggested in the many articles. Very few extensive, random series have been reported, containing mild ambulatory patients as well as the severely ill and hospitalized. Lyons and Garlock[85] showed how one can vary the same sets of figures to produce different percentage results. We believe that the actual occurrence of cancer in ulcerative colitis is probably about twice the expected incidence of cancer occurring in the general population. This would make it a potential threat but not an indication, by itself, for surgical intervention. Although cancer in ulcerative colitis can be anticipated, it cannot be predicted with certainty.

Palpable Mass or Stricture

On the other hand, cancer can be hidden in the colon of a patient with ulcerative colitis and be confused with the symptoms and signs of the colitis. Therefore, any mass or stricture which cannot be reached by the sigmoidoscope for histologic evaluation must be suspected of being cancer. Too often, an infiltrating cancer of the colon or rectum has masqueraded as a benign stricture complicating ulcerative colitis. Such neoplasms are sometimes branded as being of exceptionally high malignancy with poor prognosis,[92,93] when in fact the poor outcome may have been due more to the length of time the growth went unrecognized (delay in diagnosis) rather than to any special lethal characteristic of the neoplasm itself.

In sum, irrefutable evidence is not yet available that ulcerative colitis is a precursor of carcinoma, but the overwhelming consensus subscribes to the view that cancer is more apt to develop in patients with longstanding ulcerative colitis. Large polypoid lesions or strictures developing in the course of disease should be suspected of being carcinoma.

Venereal Disease

Many of the presumed carcinogenic factors found in chronic ulcerative colitis are also discernible in venereal lymphogranuloma involving the bowel: continuous destruction of the mucosa caused by an inflammatory process with simultaneous attempts at regeneration and the accompanying stricture, particularly in the rectum. In addition, fistulization which is often present is another possible precursor to cancer. *In brief, the essential intestinal lesions consist of ulcerations; proctitis; segmental (particularly left-sided) or even universally distributed colitis; localized suppurations; anal, anoperianal, anorectal, rectoperineal or rectovaginal fistulas, and intestinal (usually rectal) strictures which may be tubular or diaphragmatic in type.*[94] The proctitis and proctocolitis, both acute and chronic, are frequently indistinguishable from nonspecific lesions. The stricture may be accompanied by fistulization or by lymphoroids (which can only be distinguished from cancer by histologic examination). The coexistence of this venereal disease with cancer of the pelvis, vulva and anorectum is apparently not fortuitous.[95] This association with malignancy is unparalleled in other venereal diseases.[96]

We have observed a number of epidermoid cancers in the rectal strictures and the various fistulas as well as adenocarcinoma above the sites of rectal strictures.

Fistulous Tracts

Chronic draining cutaneous fistulous or sinous tracts of long standing located anywhere in the body, e.g., thoracic, abdominal or osseous (osteomyelitis), have been known to be the seat of malignancy. Chronic irritation or a growth-promoting factor in inflammatory exudates is believed to be the carcinogenic cause.[97] We have observed epidermoid and colloid cancer in: (1) untreated anal fistulas as well as in fistulotomy scars; (2) suppurative hidradenitis; (3) donovanosis, and (4) venereal lymphogranuloma in the presence of rectal strictures, draining sinous tracts and/or fistulas. We have not encountered cancers in similar fistulous tracts found in association with chronic ulcerative colitis. These considerations are our motivation for more aggressive and earlier elimination of fistulous and sinous tracts whenever possible.

Recently the occurrence of cancer in draining pilonidal sinuses of long duration has been reported.[98,99]

Diverticulitis and Leucoplakia

Cancer with obstruction of the colon may precipitate inflammation in concomitant diverticula. However, at the time of this report there is still considerable uncertainty as to what extent diverticulitis is incidental or etiologically directly contributory to the infrequent occurrence of cancer in the segment of the colon involved in diverticulitis or to the still rarer occurrence of cancer within the diverticular pouch.

Leucoplakia is considered a precursor to malignancy by some authors and denied or questioned by others.

Condyloma Acuminatum

Malignant degeneration of this lesion is occasionally reported.[100] However, Young[101] in a series of studies has reported that he has never observed cancer of the rectum in the presence of condylomata acuminata (viral warts). He believes that these lesions confer an immunity against cancer in the terminal bowel in "the same manner as vaccinia protects against small pox."

Nonunion of the Surgical Neck of the Humerus

Method of Internal Fixation

FRACTURES OF the surgical neck of the humerus may present a problem because of difficulty in obtaining and holding a satisfactory reduction. The majority of these fractures are well treated by nonoperative methods. However, there is the occasional fracture, which has to be internally fixed initially, and others which have gone on to a nonunion, necessitating operation.

The operative treatment of these fractures with Rush pins[3] in most cases gives satisfactory results. At times, however, Rush pins do not maintain adequate reduction so that other methods have to be considered. Methods previously advocated have included circumferential wires,[4] screws,[2] and a blade plate.[1]

Patients with established nonunions of the surgical neck present a more difficult problem because of the need of secure fixation while retaining shoulder motion. A shoulder spica maintains immobilization,[5] but shoulder motion suffers during the prolonged period of immobilization. The use of a blade plate according to the method of Bosworth offers a secure method of internal fixation. However, in a nonunion, the humeral head is severely osteoporotic and there is danger that the blade will cut out of the head, if early motion is attempted. Since in nonunion cases shoulder motion is usually compromised, early motion postoperatively is a prerequisite for a good result. To combat the tendency for the blade plate to cut out of the humeral head, we modified the plate in the following manner. One inch was removed from the blade, and this end was then rounded off so that one and three-sixteenth inches of the blade remained. An oval slot, slightly larger than a three-sixteenth-inch Rush pin, was made in the blade and located just distal to the middle of the blade.

Operative Procedure

Bicortical cancellous bone strips were removed from the ilium. A Henry shoulder-strap incision was made, and the deltopectoral interval developed. The deltoid was retracted laterally, and the fracture site identified. All fibrous and synovial-like tissue between the fracture ends was removed, and the bone ends were opened by drilling.

The blade end of the plate was inserted into the humeral head below the rotator cuff

and angulated medially and superiorly. The shaft of the plate was aligned with the humeral shaft. The extreme porosity of the humeral head enabled the blade to cut out of the head easily with abduction of the shoulder. A small incision was made through the rotator cuff, and a three-sixteenth-inch Rush pin was inserted down through the humeral head and passed through the oval slot in the blade into the distal humeral fragment. Insertion of the Rush pin through the oval slot in the blade is easy. Since the working area involved is small, the exact position of the slot is readily ascertained. (In cadavers we used small Kirschner wires to pass through the humeral head and find the slot. However, in the actual operation this was not necessary.)

After the passage of the Rush pin, the plate was then affixed to the humeral shaft with screws. Even with abduction done at the operating table, the blade plate was

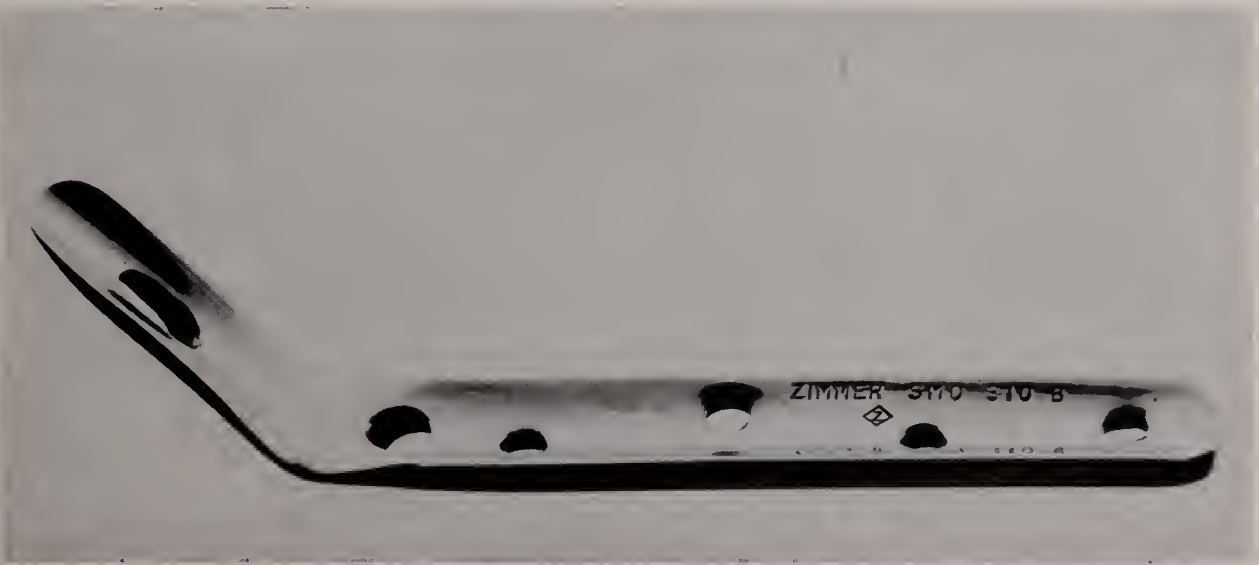

Fig. 1 — Oblique view of blade plate showing short blade and the slot cut in the blade.

securely fixed to the head and shaft. The bone graft was applied around the fracture area, and closure of the wound was done in the usual manner. The arm was put in a sling and swathe for three weeks. Circumduction exercises were then started and the sling maintained for another two to three weeks. Free motion was then allowed.

Case Reports

Case 1.

A 59-year-old male was admitted to the hospital on December 6, 1958. Two days prior to admission he sustained a fracture of the left olecranon and distal radius, plus a comminuted fracture of the left humeral surgical neck. The olecranon was fixed internally; both it and the radius healed without subsequent difficulty. The humoral fracture was never well reduced, but was held in a posterior splint with a sling and swathe. He was started on circumduction exercises at three weeks.

Outpatient visits in February and April revealed a painful nonunion with no shoulder motion. In April a bone graft was applied along with internal fixation consisting of a modified blade plate and Rush pin. There were no postoperative complications. At three weeks he was started on circumduction exercises and left the hospital several days later against advice. He did not return until September 1959, when he presented with a solid union of the humerus, 80 degrees of abduction and no pain. Both the blade plate and Rush pin were then removed, and three months later he had 120 degrees of active abduction.

Case 2.

A 71-year-old male fractured his right humerus in January 1961. A sling was applied and discarded after several months. When first seen at the hospital on June 7, 1961, he had less than 10 degrees of shoulder abduction. A spike of the humeral shaft protruded near the coracoid process, and the shoulder was extremely painful. The humeral head could be moved freely in the glenoid. X rays disclosed a nonunion.

Operation was performed on June 13, 1961. A nearthrosis was found, and fixation plus a bone graft was applied as previously described. He was held in a sling and swathe for three weeks and then started on circumduction exercises. At five weeks the patient was allowed full use of his arm. A small stitch abscess was opened at six weeks and healed quickly. At this time the patient was free from pain and had 30 degrees of abduction. Eleven weeks after operation bony union was present both clinically and by X ray. At twelve months he had 90 degrees of active abduction with no pain. The absence of normal abduction seemed to be related to decreased muscle strength and soft tissue contracture, since the Rush pin did not impinge on any overlying bony structure when the arm was abducted.

Case 3.

A 69-year-old male fractured the surgical neck of the right humerus in August 1960. He was treated in a sling and swathe but did not return for follow-up care. In July 1961 he returned to the Minneapolis General Hospital with a painful shoulder and no active shoulder abduction. A nonunion of the surgical neck of the right humerus was seen on X ray.

Operation was performed on his right shoulder on July 7, 1961, and internal fixation plus a bone graft was applied as outlined. The postoperative course was uneventful, and by October 1961 he had 45 degrees of abduction and bony union, and he was free from pain. After twelve months he had 90 degrees of active motion. Again abduction seemed related to lack of muscle power and fibrous tissue contracture.

Comments

None of the patients have normal shoulder motion. However, with the nonunion and lack of abduction before operation, the end results appear satisfactory. Using the blade plate alone gave firm fixation of the humeral head to the shaft, and without early motion this fixation would have sufficed. With motion the blade cut out of the osteoporotic head. The Rush pin through the slotted blade stopped this, and early motion could be

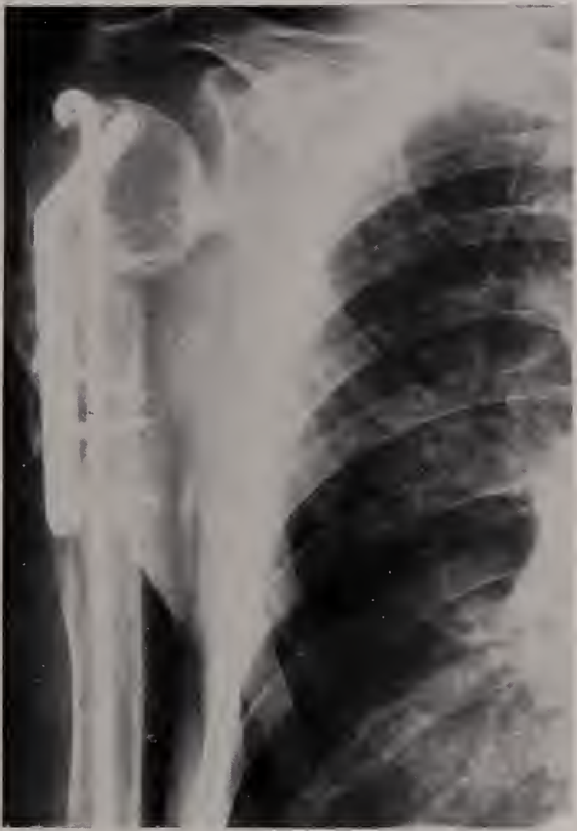

Fig. 3 — (Case 2) Roentgenogram of right shoulder made in August 1961, two months after internal fixation and bone grafting. The Rush pin is through the slot in the blade plate.

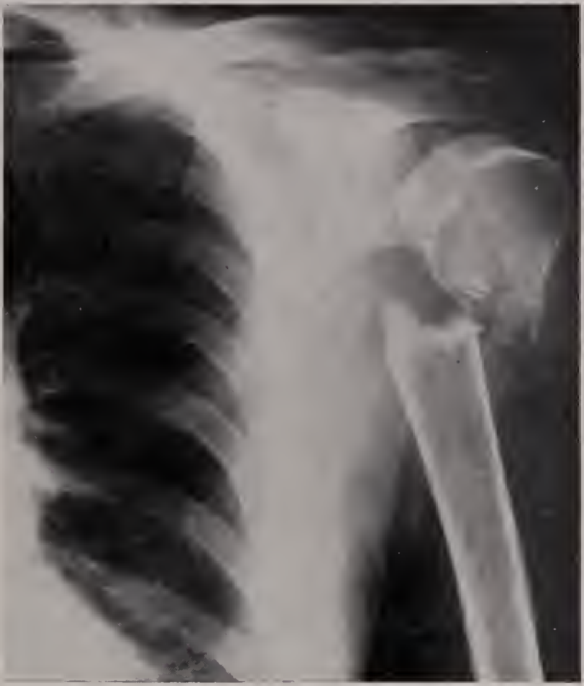

Fig. 4 — (Case 1) Roentgenogram made January 14, 1959, showing inadequately reduced left humeral neck fractures and early callous formation.

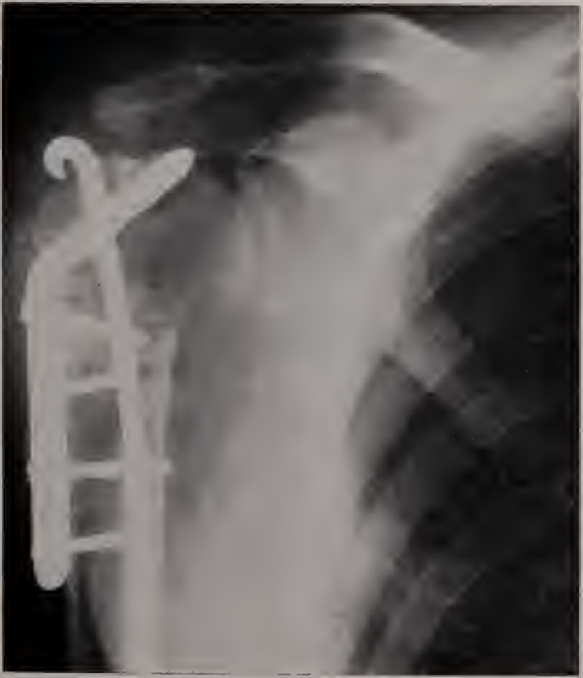

Fig. 5 — (Case 1) Roentgenogram made in June 1959, two months after operation. The blade end of the plate was too long, necessitating removal of the plate after bony union.

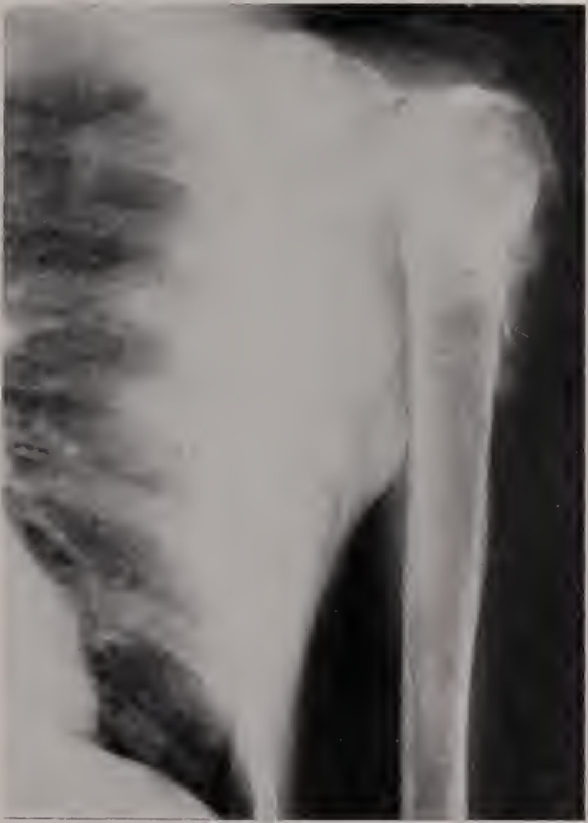

Fig. 6 — (Case 1) Roentgenogram made in October 1959, following removal of internal fixation devices. Solid bony union and good position of fragments is shown.

achieved along with bony union. The insertion of the Rush pin is technically easy and adds little time to the procedure. It is possible that late removal of the pin will aid abduction in some patients.

Summary

Three cases of nonunion of the surgical neck of the humerus are presented to illustrate a new modification of the blade-plate fixation technique. In each case solid bony union was achieved along with improvement in the range of motion at the shoulder.

NOTE: We extend our thanks to the Minneapolis Veterans Administration Brace Shop for the modification of the blade plate, and to Doctor Joseph Kiser, of the Minneapolis General Hospital, for permission to report his case.

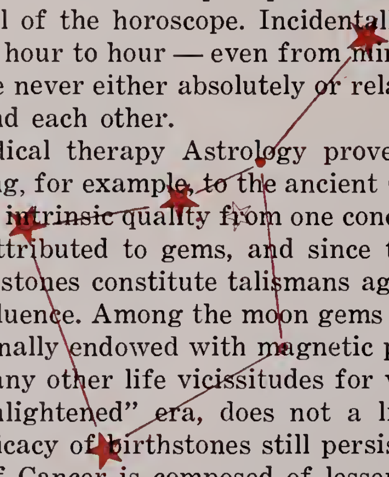
Astrology and Medicine — Cancer, the Crab

Cancer, the Crab, whose stellar configuration is here delineated, is the nativity sign for those born between June 22 and July 22, when the sun is domiciled in that constellation. Astrologically, Cancer governs the breast and gastric regions, and consequently is responsible for the health or disease of those parts — depending on the presence or absence of benefics and/or malefics, and also on the complex pattern of their mutual aspects within the total wheel of the horoscope. Incidentally, the intricate wheel pattern changes from hour to hour — even from minute to minute — since the celestial bodies are never either absolutely or relatively stationary with reference to Earth and each other.

In the field of medical therapy Astrology proves to be versatile and adaptive — subscribing, for example, to the ancient Chaldean theory of the occult transmission of intrinsic quality from one concrete object to another. Special virtues are attributed to gems, and since the ruler of Cancer is the moon, the moon's stones constitute talismans against afflictions due to adverse Cancerian influence. Among the moon gems are emeralds, crystals, and pearls — traditionally endowed with magnetic power against not only the diseases but also any other life vicissitudes for which Cancer is culpable. Even in this "enlightened" era, does not a lingering, if irrational faith in the magic efficacy of birthstones still persist?



The constellation of Cancer is composed of lesser magnitude stars and is difficult to locate in the sky, overshadowed as it is by its predecessor, Gemini, and its follower, Leo — both more brilliant and dominant. Though not dramatic, Cancer is distinctive for having nestled in one of its angles the stellar cluster, Praesaepe, popularly known as The Beehive. In spite of its relative dimness, however, Cancer, the Crab, can be identified by the patient and careful scrutinizer of the southern ecliptic during clear March evenings. A star guide of the heavens is always helpful.

Congenital Heart Disease

Diagnosis of*

LEWIS S. CAREY, M.D.**
St. Paul, Minnesota

THE SPECTRUM of anatomical malformations in congenital heart disease ranges from an isolated obstruction or an isolated opening in a major vessel or outflow tract to a complex combination of abnormal obstructions or openings at multiple sites which may be associated with an abnormal position of the heart and/or great vessels. The type and extent of diagnostic evaluation in congenital heart disease depends in part upon the suspected complexity of the anomaly and in part upon the orientation and experience of the individuals engaged in the diagnosis. For example, in certain patients without cyanosis some institutions may rely primarily on clinical, radiographic and electrocardiographic findings. Other institutions may commonly employ additional studies such as cardiac catheterization and/or angiocardiography; the emphasis placed on these two procedures varies from place to place. Angiocardiography is becoming increasingly emphasized since it is a direct method of demonstrating pathologic anatomy and provides a qualitative visual picture of the altered hemodynamics. Such demonstrations are appreciated by the surgeons who can actually see the lesions and are a delight to radiologists whose basic interest lies in the art of demonstrating hidden structure both normal and abnormal.

As a general rule, the more clinically complex the lesion, the more useful is angiocardiography. It is the procedure of choice in cyanotic heart disease where unusual patterns of flow often preclude accurate interpretation of physiologic catheterization data.

The nature of a suspected cardiac lesion is obviously important. It may be equally important, however, for the rural practitioner to recognize the necessity of sending a child to a center for cardiac evaluation and, if so, how urgently.

The answer lies, in part, in the examination of the routine roentgenogram of the thorax.

Cardiac Enlargement

Minor degrees of cardiomegaly are difficult to appreciate. A frontal chest film exposed during expiration may reveal what appears to be a "bulky" heart. A film, exposed in the same patient during inspiration, may show the true situation of a perfectly normal-sized heart. Occasionally a large thymus gland hugging the base and the sides of the heart may mimic cardiomegaly. A close examination of the heart border will often reveal a slight prominence which represents the overlapping lower margin of the thymus.

---

*Presented at the Minnesota State Medical Association Annual Meeting in Rochester, May 19, 1964.

**Assistant Clinical Professor, Department of Radiology, University of Minnesota and Director Cardiovascular Diagnostic Unit, Department of Radiology, St. Joseph's Hospital, St. Paul, Minnesota.

Failing this, a brief fluoroscopic examination during a maximal inspiratory effort at the end of a cry will reveal a decrease in the volume of tissue about the base of the heart, indicating its identity as thymus. Rarely will a mediastinal tumor closely applied to the heart give the impression of cardiomegaly.

Pulmonary Vessels

A most important part of the interpretation of the chest film has to do with the pulmonary vasculature. Four basic patterns are seen.

Increased Pulmonary Vasculature

First and most common is increased pulmonary vasculature. Anomalies associated with a left-to-right shunt and increased pulmonary flow are characterized roentgenographically by an increase in the size of the pulmonary trunk and accentuated pulmonary vasculature. The shunt may be intracardiac, as occurs, for example, in defects of the atrial or ventricular septum; or it may be extracardiac, resulting from a communication between the great vessels such as patent ductus arteriosus or aortic-pulmonic window.

All of these conditions, at some time or another, may be accompanied by or develop an increase in pulmonary vascular resistance and pulmonary hypertension. When this state is established the pulmonary trunk and central pulmonary vasculature become strikingly prominent, while the peripheral pulmonary vasculature becomes attenuated. The stage has been set for the development of a right-to-left shunt, and cyanosis may become apparent.

Certain so-called admixture lesions (obligatory bidirectional shunts), such as complete transposition, common ventricle, total anomalous pulmonary venous connection and truncus arteriosus, are characterized by increased pulmonary vasculature. Most often these patients are recognized soon after birth because of cyanosis.

Diminished Pulmonary Vessels

The second pattern, that of diminished pulmonary vasculature, is usually the direct result of obstruction to pulmonary flow. Examples of such anomalies include the tetralogy of Fallot, tricuspid atresia and pulmonary atresia.

Normal Pulmonary Vessels

The third pattern, that of normal appearing pulmonary vasculature, occurs in those conditions associated with obstructions on the left side of the heart, for example: aortic stenosis, coarctation, and fibroelastosis. When these anomalies are severe, pulmonary congestive changes may appear.

Obstruction to Inflow

The fourth pattern of the pulmonary vasculature is seen in those conditions characterized by obstruction to the inflow of pulmonary venous blood. Cor triatriatum,* obstruction of the pulmonary veins and congenital mitral stenosis may cause a diffuse increase in the density of both lung fields or a fine, central, pulmonary streaking with poor definition of individual vascular markings.

Alteration of Cardiovascular Contour

As a general rule abnormal positions of the heart (dextroversion and dextrocardia) are associated with other cardiac anomalies, and often the prognosis is poor.

Normally the left cardiovascular silhouette is formed from above downward by the aortic knob, the pulmonary trunk and the left ventricle. The right silhouette is formed by the superior vena cava above, and the right atrium below.

The subtle variations in contour are as numerous as the types of congenital heart lesions. There are, however, some bold alterations which are diagnostically significant. The most obvious of these are the result of a change in size or position of the great vessels.

Ventricular Septal Defects

Enlargement of a great vessel is usually the direct result of either increased flow or partial obstruction; an opinion as to which of these states is responsible must necessarily be based on the appearance of the pulmonary vasculature. This is particularly true in the case of the pulmonary trunk. For example, in ventricular septal defect and left-to-right shunt there may be obvious enlargement of the pulmonary trunk; the presence of increased pulmonary vasculature suggests that the enlargement is due to increased flow. When ventricular septal defect is associated with pulmonary hypertension there is often striking enlargement of the pulmonary trunk, caused in this instance by a combination of increased flow and an element of obstruction, the latter resulting from an elevated pulmonary resistance secondary to occlusive changes in the pulmonary vascular bed.

---

*See Test Your Word Score Page 359.

Pulmonary Stenosis

In severe pulmonary stenosis the pulmonary trunk may become very large. In this situation, however, the mechanism is different. The dilatation results from turbulence and abnormal pressures on the wall of the pulmonary trunk distal to the valvular stenosis — so-called poststenotic dilatation. In such a case the pulmonary vasculature may be diminished,, suggesting that the cause of the enlargement is one of partial obstruction to flow.

Tetralogy of Fallot

Aortic enlargement in the presence of diminished pulmonary vasculature usually indicates the presence of obstruction to pulmonary flow in association with a right-to-left shunt at either the atrial or ventricular level. The common example in this category is the tetralogy of Fallot. Less common anomalies showing somewhat similar features are pulmonary atresia and tricuspid atresia.

Congenital Valvular Aortic Stenosis

Obvious enlargement of the ascending aorta in the presence of normal-appearing pulmonary vasculature should arouse suspicion of a left-sided lesion. A common anomaly of an obstructive nature causing poststenotic dilatation of the aorta is congenital valvular aortic stenosis.

Diminished size of the great vessels may on occasion result in an alteration of cardiovascular contour. Detection of such, however, is often impossible in the infant because the vessels are frequently obscured by the thymus. Once the thymus gland undergoes involution, decreased size of the outflow portion of the right ventricle and pulmonary trunk, as occurs, for example, in the tetralogy of Fallot, will result in a distinct concavity of the upper mid-portion of the left cardiovascular silhouette. Detection of diminished aortic size in roentgenograms of the thorax is very difficult, if not impossible.

Malposition of the Great Vessels

Finally, malposition of the great vessels may result in contour alteration. For example, those cases of complete transposition with an anteroposterior relationship of the great vessels will show a narrow cardiac "waist." In corrected transposition the aorta arises anteriorly from the base of the heart on the left side. The pulmonary trunk is medially located.

Summary

When the information from a careful radiologic examination of the heart, great vessels and pulmonary vasculature is combined with the clinical findings, a big step may be taken toward the diagnosis and a very important decision can be made concerning the disposal of the patient.

Obviously cyanotic patients require an early, definitive diagnosis to separate the potentially correctable from the noncorrectable case.

On the other end of the spectrum is the noncyanotic patient with a murmur, but with absent or minimal radiologic signs and no disturbing clinical signs such as: decreased exercise tolerance, poor weight gain, intermittent pulmonary infections and cardiac decompensation. In this situation there is usually no urgency for cardiac evaluation. Observation, periodic radiologic and electrocardiographic examinations will often show no sign of change, and additional studies may be deferred until the child is older.

In contrast, an aggressive attitude is best when in noncyanotic patients there are signs of developing pulmonary hypertension, since this is the main factor which determines operability and ultimate prognosis. The two most important observations, short of cardiac catheterization, which will suggest the presence of pulmonary hypertension, can be made with the use of the stethescope and the roentgenogram. An increase in loudness and snapping of the pulmonary second sound in concert with increasing size of the pulmonary trunk and central pulmonary vasculature accompanies this undesirable development.

The same aggressive attitude should pertain when in children signs of cardiac failure appear; not uncommonly the underlying cause is a correctable, obstructive left-sided malformation.

SHEEHAN'S SYNDROME

(Postpartum pituitary necrosis)

Panhypopituitarism is due to postpartum thrombosis of sinuses and ischemic infarction and necrosis of the pituitary gland. It is suggested that the syndrome occurs much more frequently than is generally recognized. If a woman suffers a severe hemorrhage, collapse, or shock at the time of delivery or during the early postpartum period, she should be observed closely for subsequent signs of pituitary necrosis. The symptoms of this condition are multiglandular, some showing myxedema. There is pallor, asthenia, apathy, atrophy of the breasts with loss of areolar pigment, inhibition of lactation, loss of public and axillary hair, and genital atrophy. Amenorrhea may be temporary or permanent. Diabetes mellitus, if present, vanishes. Hypoglycemia is usually found and may be sufficiently severe to produce coma. A flat glucose tolerance curve and extreme sensitivity to insulin may be demonstrated.

There is a reduction in the excretion of the corticoids in the urine and when both the anterior and posterior lobes of the pituitary have been involved, there may be a marked diminution in the gonadotropins, thyrotropins, and corticotropins accounting for the descriptive term "panhypopituitarism."

Treatment should be directed to polyglandular administration. If potent, dependable pituitary extract is not available, then cortisone or hydrocortisone with dersecated thyroid and estrogen replacement will give varying results from satisfactory to excellent.

The Penalty of Overweight

In autopsy studies it has been demonstrated that there is a close association between obesity and atherosclerosis with advanced degrees of arterial changes being found twice as often among the obese as among the poorly nourished individuals.

The Natural History of Cholelithiasis

*A 15 to 30-Year Follow-up of 116 Patients**

DONALD E. RALSTON, M.D.**
LUCIAN A. SMITH, M.D.**
Rochester, Minnesota

DESPITE THE voluminous literature on disease of the gallbladder there is no uniformity of opinion concerning the advisability of cholecystectomy in the patient with gallstones. Recommendations range from operation on all patients with cholelithiasis, on the assumption that "there are no innocent gallstones," to operation on only those with troublesome symptoms or complications.

In an attempt to determine what our advice to patients with cholelithiasis should be we have collected information on a group of patients who for any reason did not have cholecystectomy at or near the time gallstones were discovered and who have been followed for 15 or more years after diagnosis or until death. By so doing we have hoped to shed some light on the natural history of cholelithiasis.

Selection of Patients

From the files of the Mayo Clinic for the years 1930 through 1945 we obtained information on consecutive patients who had cholelithiasis but did not undergo cholecystectomy during the clinic admission in which that diagnosis was made. No diagnosis of cholelithiasis was accepted unless gallstones had been visualized by radiography or had been palpated at operation for another condition. We excluded those patients in whom cholecystectomy was performed as the result of the original medical advice, even though that operation was initially deferred, unless the patient returned because of additional symptoms. We chose only those patients with a local address (Rochester, Minnesota) in order to eliminate the selectivity of referred patients.

TABLE I
Cholelithiasis: Status of 116 Patients Not Operated on at Time of Diagnosis

*Associated acute pancreatitis.

---

*Read at the meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 10, 1964.

**Section of Medicine, Mayo Clinic and Mayo Foundation.

Records of 132 patients meeting these requirements were obtained, and in 116 (88 per cent) of these we were able to acquire adequate information concerning the subsequent course until death of the patient or for 15 or more years after the diagnosis had been made. Of these 116 patients, 104 were females and 12 were males.

Results

One hundred two of the 116 patients with cholelithiasis were *symptomatic (88 per cent)* at the time of diagnosis and 71 (70 per cent) of these had had pain. Only 14 (12 per cent) could have been considered as having "silent" gallstones (Table 1). Age distribution at the time of diagnosis followed an anticipated pattern with 93 of the 116 cases of gallstones being discovered in the *fourth through seventh decades of life (80 per cent)*. In 25 cases *surgical treatment was considered inadvisable (22 per cent)* because of other illness, obesity or old age. No attempt was made to evaluate in each of the other cases the degree to which the need for operation was emphasized to the patient, although it was evident that this varied widely among the physicians involved.

Table 2 summarizes the status of the 116 patients followed for 15 or more years subsequent to the diagnosis of cholelithiasis or until death. At the conclusion of the study 63 patients were still living and 53 had died. Fifty-nine of the total number had had an *operation on the gallbladder (51 per cent)*, 56 of them because of symptoms attributed to gallbladder disease, two because cholecystectomy was indicated and feasible at the time of other intra-abdominal operations, and one for unknown indications. For any one decade of life in which gallstones were discovered the percentage of patients eventually having an operation roughly paralleled the life expectancy for that age. Of the 27 patients with cholelithiasis discovered when the patient was less than 40 years of age, 23 had cholecystectomy before termination of the follow-up-period (85 per cent); of the 52 patients less than 50 years of age, 38 eventually had an operation (73 per cent), and of the 78 patients less than 60 years of age, 52 underwent operation (67 per cent).

Fifty-seven of the 116 patients had not been *operated on by the end of the follow-up period (49 per cent)*, but seven of these were having persistent severe symptoms (Table

TABLE 2
Cholelithiasis: Status of 116 Initially Unoperated Patients
After 15 to 30 Years

3). Of the 14 patients who were asymptomatic at the time of diagnosis, 10 remained asymptomatic and two required surgical treatment eventually; but of the 102 patients who were originally symptomatic 57 (56 per cent) eventually had had an operation, most of them because of severe symptoms. Ten of the 26 patients with cholelithiasis whose gallstones had been discovered when the patients were less than 60 years of age, but who had not had gallbladder surgery, were having varying degrees of indigestion or pain or both up until death or the end of the follow-up period, but in only three of these were symptoms severe and frequent. Of the 25 patients who were advised not to have surgical treatment because of ill health, marked obesity or old age, only two eventually required it.

None of the patients in this series died as a result of surgical treatment. Three died as the direct result of gallbladder disease: two because of carcinoma of the gallbladder and one because of rupture of the gallbladder.

Asymptomatic	14	12	1
Indigestion only	31	19	3
Pain	71	26	3
Total	116	57	7

Discussion

Observations in large post-mortem series have shown the incidence of gallstones to be about 10 per cent in all people more than 20 years of age and about 30 per cent in white females and 15 per cent in white males in the seventh decade of life, with less than half that incidence seen among Negroes.[1-6] Physicians have been finding only a small proportion of these during life. If we really believe that gallstones carry a high risk, then we should be surveying the general population beyond the age of 40 or 50 years and advising all of those with gallstones, whose health permits, to have cholecystectomy. Obviously we have not been doing this, probably because it seems unrealistic either to obtain cholecystograms or to consider cholecystectomy in such large numbers. The universal result is that cholecystograms are usually obtained only when symptoms suggest that disease of the gallbladder may be present.

Indications for Surgery in Patients With Symptoms

There is quite uniform agreement that all patients with gallstones who have associated serious complications such as jaundice, acute cholecystitis or pancreatitis should be operated on. Most of us will agree that the patient with repeated attacks of colic or troublesome indigestion or both, which can be presumed to be associated with his gallbladder disease, should be advised to have cholecystectomy if his health permits. From this study it seems obvious that the younger the patient when symptoms lead to the diagnosis of gallstones, the more likely it is that he will eventually require surgical treatment. Of those less than 60 years of age when the diagnosis of gallstones was established, 67 per cent eventually required an operation on the gallbladder, and there was an abrupt drop in the percentage requiring an operation when the diagnosis was made after that age. It therefore seems reasonable to advise cholecystectomy in the patient less than 60 years old with symptomatic gallstones. In those more than 60 or 65 years of age we believe that the decision concerning operation must be individualized.

Our main area of indecision remains, as it has since the beginning of this century, in what to advise the patient with silent gallstones or whose gallbladder disease has caused only mild symptoms or a single episode of colic.

Indications for Surgery Without Symptoms

There has accumulated considerable statistical information which adds great weight to the opinion that all gallstones should be removed when they are found. For example, Enderlin[7] in a large post-mortem series found that 40 per cent of those with gallstones had complications from them and that these complications were the cause of death in 8.7 per cent and were contributory causes in 7.8 per cent. Post-mortem studies have also shown a 4 to 5 per cent incidence of carcinoma of the gallbladder in patients with gallstones beyond the age of 60 years, although clinical series including all age groups in recent years show an incidence closer to 0.5 per cent.[8-10] Mortality rates for cholecystectomy increase with age, particularly in the over 65 group, and complications such as acute cholecystitis, pancreatitis and jaundice cause a manyfold increase in risk even in the best of hands. Comfort and colleagues[11] in a 10 to 20-year follow-up of 112 patients with silent gallstones that had been discovered at operation for other conditions found that 51 had developed symptoms and that 24 of these had required cholecystectomy, with three deaths postoperatively.

Although these representative figures from the literature would encourage us to consider cholecystectomy in asymptomatic cholelithiasis, Robertson's[12] words of caution in 1945 are still worth listening to: *"to advocate an operation on every gallbladder that is found to contain gallstones is so drastic a recommendation that it would appear reasonable for the proponents of this advice to reexamine the premises on which it is based."* It is not enough to point out that a sizable percentage of patients with asymptomatic gallstones will eventually require an operation, that the risk of operation increases with age and with complications, or that a significant number will die as the result of gallbladder disease, especially in old age. It is necessary to be able to compare the risk of operation in a group of patients with asymptomatic gallstones at a given age with the risk in that same group in which a certain percentage of patients unoperated on for gallstones will later either become symptomatic and/or develop complications that require surgical treatment with increased risk. It would also seem advisable to be able to calculate the man-years of life expectancy lost because of the surgical mortality in asymptomatic gallstones and compare this with the man-years lost if surgical treatment is deferred until it becomes mandatory or until disease of the gallbladder causes death.

Surgical Mortality

To search out all people who have gallstones means that each individual would require multiple cholecystograms during his lifetime. A prerequisite to operation on all those who develop gallstones would be a lower mortality rate for cholecystectomy than the anticipated mortality rate for disease of the gallbladder as it is handled in this country at present. The Metropolitan Life Insurance Company lists the average annual death rate for diseases of the gallbladder as 3.8 per 100,000 for both white men and women aged 35 to 74 in the period 1960-1962;[13] this means that an individual aged 45 years with a life expectancy of 30 years stands a 0.11 per cent chance of death from gallbladder disease before age 75. If the combined average incidence of gallstones in white men and women at age 45 is 10 per cent, then the risk of death from gallbladder disease in patients with gallstones and a 30-year life expectancy is about 1 per cent. The surgical mortality in uncomplicated cholelithiasis should be no more than half of this. Whether these calculations would have differed significantly if only patients with asymptomatic gallstones had been considered is a matter only for conjecture. However, Lund[14] concluded, in his series of patients with gallstones who were not treated surgically and were followed for five to 20 years after diagnosis, that the prognosis for those with asymptomatic stones was not much better than that for patients with other types of the disease.

Nevertheless, the figures available suggest that not more than one out of every four or five patients with gallstones will ever require surgical treatment for them,[11,14,15] and that therefore a four or fivefold mortality rate in the 20 to 25 per cent of patients eventually requiring an operation would not exceed the total mortality rate if all patients with asymptomatic gallstones had been operated on. Unfortunately, there are no large long-term studies available on people with asymptomatic gallstones to show the comparative risks.

Morbidity in Lost Man-years

We have been speaking only of mortality rates without taking into consideration the age at which death occurs. We should include in our calculations the risk rate in terms of man-years lost because of surgical mortality at the time asymptomatic gallstones are discovered and contrast this with the surgical risk rate at a later age when some of those same gallstones have become symptomatic and some complicated, adding to this the death rate from gallbladder disease itself. For example, in terms of man-years lost, the surgical loss of a young patient with 40 years of life expectancy would equal the loss of four older patients each with 10 years of life expectancy. In this connection it is well to recognize that if we are to advise surgical treatment for silent gallstones, the total man-years lost by operating during a low-risk situation may outweigh that by delaying operation until it becomes necessary. The greatest risks in gallbladder disease are in old age when surgical risks increase and carcinoma of the gallbladder develops, but it is also then that life expectancy is least.

A corollary to this is an intangible factor which no figures can answer. This pertains to the value of a year of life at various ages. For example, we believe all would agree that the value of a year to a woman in her 40s with a family might be greater than a year in her 60s when her children have been educated and are self-sufficient. If this be true, it is an added factor in avoiding operation at a time when a currently benign condition is asymptomatic.

There are certain situations in which we believe that cholecystectomy in the patient with asymptomatic gallstones should be seriously considered: (1) when the gallbladder is nonfunctioning on cholecystography; Clagett[16] found that 27 per cent of a series of 150 such patients who originally refused operation were forced to undergo one for serious complications such as jaundice, pancreatitis and perforated gallbladder within two years after the diagnosis had been made; (2) when gallstones are present in a patient with a troublesome duodenal ulcer; (3) when abdominal exploration is undertaken for another condition and cholecystectomy is feasible without undue increase in risk; and (4) probably when multiple small stones are demonstrable.

The search for gallstones in the general population, even if confined to limited age groups, would be expensive and time-consuming and would require the conviction of all physicians that cholecystectomy in asymptomatic cholelithiasis is not only justified but imperative. Cholecystectomy even when uncomplicated would necessarily result in small but significant morbidity and mortality rates in a relatively young, asymptomatic, productive and active segment of the population and unfortunately would leave some individuals with unpleasant postoperative symptoms. We do not believe that there is as yet certain statistical evidence which makes cholecystectomy advisable in the asymptomatic patient with gallstones, nor do we believe that a routine search for gallstones is a realistic undertaking at present.

Conclusions

The younger the age at which gallstones are discovered the greater is the probability that cholecystectomy will become necessary eventually. In this reported series of patients with gallstones, two thirds of those less than 60 years of age when the diagnosis was established required surgical treatment later.

All patients less than 60 years of age who have gallstones with significant associated symptoms should have an operation if general health permits.

After the age of 60 years the likelihood that cholecystectomy will be necessary before death occurs from a cause other than gallbladder disease, is sharply reduced, and therefore the decision concerning operation should be individualized.

Mortality rates should be calculated in terms of man-years of life expectancy lost when the advisability of cholecystectomy for silent gallstones is considered.

The decision concerning cholecystectomy in patients with asymptomatic gallstones remains unsettled except for a few specific indications, which are listed. We believe that the routine search for asymptomatic gallstones and cholecystectomy in all patients in whom they are discovered is unjustified at present.

WHAT'S YOUR DIAGNOSIS?

A 64-year-old white male patient had a stroke about five years prior to hospital admission with residual aphasia and paralysis of the left upper extremity. Three weeks prior to his admission he had suddenly started having painless jaundice, associated with "coca-cola" colored urine. His relatives had not observed the color of his stools. His temperature was normal throughout this period. His relatives denied that he had any previous history of weight loss or any abdominal discomfort. No food intolerance was noted. The patient was a diabetic, controlled with Orinase. He had been admitted to another hospital with diagnosis of viral hepatitis and subsequently transferred here.

Physical Examination: The patient was a well-nourished white male with aphasia and with paralysis of the upper right extremity; he was jaundiced but not in acute distress. The abdomen was very slightly distended. Liver and spleen were not palpable. No tenderness was found. No tumors were felt. The rest of the physical examination was essentially negative.

Pulse 92, regular. Blood pressure 110/80. Temperature 99.5, orally. Respiration Rate, 24/min., regular.

Laboratory Work-up: Prothrombin Time, 15 sec. Transaminase: 140, Glucose, 158; Bilirubin Total 21.8, direct 18.9. Thymol Turbidity, 1.2. units; Alkaline Phosphatase 21.5 King Armstrong unit, Urine Urobilinogen 0, repeated .46. An upper G. I. series was reported, normal.

Hospital Course: The patient's condition did not change. His jaundice stayed about the same clinically. On the seventh day after his admission, he was taken to surgery.

Results of Cholecystostomy in the Treatment of Acute Cholecystitis

EUGENE C. WEINSTEIN, M.D.*
HARRY N. HOFFMAN, II, M.D.**
W. SPENCER PAYNE, M.D.***
Rochester, Minnesota

For some medical complications and technical hazards cholecystostomy is a helpful procedure.

CHOLECYSTOSTOMY IS not a new method for the treatment of gallbladder disease.[1] During the last 15 years there have been numerous reports describing its use in various biliary tract conditions.[2-5] The present report concerns the use of cholecystostomy for acute cholecystitis alone, with particular emphasis on the medical and technical indications for the choice of this procedure.

For this study, the records of all patients treated surgically for acute cholecystitis at the Mayo Clinic in the 7-year period from January, 1951, through December, 1957, were reviewed. Particular emphasis was placed on the indications for and results of cholecystostomy in this group. The clinical diagnosis of acute cholecystitis was confirmed in each case by the findings at operation and, in some cases, by review of pathologic material removed at operation.

During this 7-year period, 7769 operations were performed for chronic cholecystitis and 446 for acute cholecystitis. In the latter group, 62 patients (14 per cent) underwent cholecystostomy. For the purposes of our study, this latter group was then divided into operations performed for medical indications (29 cases) and those performed for technical indications (33 cases). Follow-up information on each patient was obtained either by subsequent examination or follow-up letters.

Cholecystostomy for Medical Indications

Twenty-nine of the 62 cholecystostomies were performed for medical indications. This represents 47 per cent of the cholecystostomies done for acute cholecystitis during the 7-year period. The ages of these patients ranged from 32 to 91 years (average, 66

***Section of Surgery, Mayo Clinic and Mayo Foundation.

years). Fifteen were men (average age, 71 years) and 14 were women (average age, 61 years). One patient had undergone cholecystostomy 28 years prior to cholecystostomy at the Mayo Clinic for recurrent acute cholecystitis.

Not only were the associated medical conditions varied, but, in most instances, the presence of multiple medical problems precluded more definitive surgical treatment (Table 1). The most frequent disorders were extreme obesity, marked coronary artery disease, severe hypertension, and advanced cerebrovascular insufficiency. Fourteen of the 29 cholecystostomies were performed as planned procedures with local anesthesia.

TABLE 1
Medical Indications for Cholecystostomy

Indication	Patients*
Extreme obesity	12
Marked coronary artery disease	11
Severe hypertension	9
Advanced cerebrovascular insufficiency	6
Rheumatic heart disease	4
Diabetes mellitus	3
Previous myocardial infarct	2
Severe toxicity	2
Emphysema	2
Asthma	1
Carcinoma of the pancreas	1
Carcinoma of the prostate	1
Myxedema	1
Squamous cell carcinoma of the lung	1
Severe burn	1
Rhabdomyosarcoma of the scapula	1

*Some patients had more than one indication.

Multiple stones were removed from the gallbladder in 20 cases; a single stone was removed in seven cases and in two cases no stones were recovered. In one case, choledochostomy was performed in association with cholecystostomy with removal of a common duct stone.

Period of Convalescence

The duration of postoperative hospital convalescence ranged from nine to 66 days (average, 21 days). Postoperative complications included asthmatic attacks (two cases), atelectasis (one case), superficial thrombophlebitis (one case), cardiac arrhythmia (three cases), and exacerbation of rheumatic heart disease (one case). There were five postoperative hospital deaths, an operative mortality of 17 per cent (Table 2).

TABLE 2
Hospital Deaths After Cholecystostomy for Medical Indications

Age	Sex	Postop. day	Cause of death
82	F	40	Anemia and azotemia
32	F	41	Cirrhosis
68	F	48	Carcinoma of pancreas
44	F	14	Electrolyte imbalance
79	M	31	Bilateral pulmonary emboli

Follow-up information was available in 22 of the 24 patients who survived operation (92 per cent). The duration of follow-up ranged from three months to 12 years (average, 3½ years). Fifteen of the 22 patients traced had not experienced recurrent biliary symptoms. Six of these asymptomatic patients survived for two to 12 years following operation, and nine died of associated medical disease within five years after operation. Three others died with no information available concerning biliary symptoms.

Incidence of Recurrent Symptoms

Three patients underwent subsequent cholecystectomy for recurrent symptoms six months to two and one-half years after the cholecystostomy; one of these patients died of carcinoma of the gallbladder three and one-half years after the initial operation.

If we include under "symptomatic patients" those who underwent cholecystectomy at a later date, those who died with no information available regarding biliary symptoms, and the patient who died of carcinoma of the gallbladder, the incidence of recurrent symptoms after cholecystostomy for medical indications was 32 per cent.

Cholecystostomy for Technical Indications

Thirty-three of the 62 cholecystostomies were performed for technical indications. This represents 53 per cent of the cholecystostomies done for acute cholecystitis during the 7-year period. The ages of these patients ranged from 35 to 86 years (average, 63 years). Twenty-one were men (average age, 66 years) and 12 were women (average age, 61 years). One patient had had two previous cholecystostomies, performed 29 and 31 years prior to treatment at the Mayo Clinic.

The major disease states that contraindicated cholecystectomy in the medical group were, for the most part, present in this group also, but less frequently and to a lesser degree of severity. Patients in this group underwent surgical exploration that was expected to lead to definitive surgical treatment for acute cholecystitis. However, at operation it was found that the degree of inflammatory reaction had so obscured and distorted the normal anatomic landmarks that the surgeon thought that attempts to remove the gallbladder would be associated with a serious risk of injury to the common duct or other portal structures; thus cholecystostomy was performed.

Multiple stones were removed from the gallbladder in 30 cases, a single stone was removed in two cases, and no stone was recovered in one case. In two patients, choledochostomy was performed in association with cholecystostomy, with removal of common duct stones in each instance.

Period of Convalescence

Convalescence was considerably shorter in this group than in those in whom cholecystostomy was performed for medical reasons; the duration of postoperative hospital convalescence ranged from eight to 30 days (average, 14 days). Postoperative complications included one instance each of wound evisceration, thrombophlebitis, acute epididymitis, atelectasis, multiple pulmonary emboli, and cerebrovascular accident. There was only one death in the immediate postoperative period, an operative mortality of 3 per cent. This patient was an 83-year-old man who died on the twenty-sixth postoperative day after progressive development of confusion.

Follow-up information was available in 27 of the 32 patients who survived operation (85 per cent). The duration of follow-up ranged from two months to 11 years (average, six years). Fifteen of the 27 patients traced had not experienced recurrent biliary symptoms. Eleven of the asymptomatic patients survived from four to 10 years after operation; four patients died of intercurrent disease from one to 10 years after operation. One patient died seven years postoperatively but no information was available concerning biliary symptoms. Two patients were alive with recurrent biliary symptoms eight and 11 years, respectively, after operation.

Incidence of Recurrent Symptoms

Nine patients have undergone subsequent cholecystectomy. One patient had a planned interval cholecystectomy six months after the initial operation. Two patients had their gallbladders removed as part of another operative procedure eight and 11 years following cholecystostomy; in neither case had there been recurrent biliary symptoms. In six cases cholecystectomy was performed for recurrent symptoms two months to nine years following cholecystostomy. In two of these six cases, stones were removed from the common duct at exploration.

If we include under "symptomatic patients" those who subsequently underwent cholecystectomy, those patients who died with no information available regarding biliary symptoms, and those alive with recurrent symptoms, the incidence of recurrent symptoms after cholecystostomy for technical indications is 44 per cent.

Discussion

Among operations performed for acute cholecystitis, cholecystostomy has comprised from 3.7 to 28 per cent[6-9] and was 14 per cent in the present series.

The group that had the operation for medical indications had a somewhat older average age than that of the group that had the operation for technical indications. Also, the average age of these patients was approximately 10 years older than that of the patients in a similar series reported earlier from this institution.[4]

The severity of the associated disease in the group in which cholecystostomy was performed for medical indications is suggested by the higher mortality, both early and late, as compared to that group in which cholecystostomy was performed solely for technical indications. The over-all operative mortality of 9.7 per cent is consistent with that of previous reports.[5,6,8] However, it should be noted that, of the eight deaths following 446 operations for acute cholecystitis, six occurred in the 62 patients undergoing cholecystostomy; 14 of the procedures were performed as planned cholecystostomies. The use of the planned cholecystostomy was recently discussed thoroughly by Sparkman.[10]

The incidence of recurrent biliary tract symptoms after cholecystostomy in the present group of patients was 39 per cent, which is considerably lower than incidences reported by others.[3,5] In both of our groups, symptoms frequently recurred a few months postoperatively, and, in two cases, cholecystectomy was performed for recurrent difficulty as long as nine years after the initial operation. Two patients had recurrent acute cholecystitis 28 and 31 years after cholecystostomy. In addition to the possibility of late recurrence of symptoms, it should be noted that even those patients who had severe medical conditions when operated on frequently had prolonged survival following cholecystostomy. In view of these facts, it would seem important to consider additional and more definitive surgical treatment for all patients undergoing cholecystostomy, to be done when their general condition permits. There were no postoperative deaths in any of the patients who had subsequent cholecystectomy in this series. However, it was disappointing to note how few patients subsequently underwent elective interval cholecystectomy.

It is apparent from this discussion that cholecystostomy is not the treatment of choice for acute cholecystitis. It is not without risk and is associated with a high incidence of recurrent symptoms. Yet, in the severely ill patient with acute cholecystitis complicating associated difficult medical conditions or in the patient operated on for acute cholecystitis in whom more definitive procedures are contraindicated for technical reasons, cholecystostomy seems to offer reasonable palliation. Experience indicates that cholecystostomy has no virtues over more definitive procedures when the latter can be accomplished expeditiously and in a technically satisfactory manner. In dealing with the individual patients it is obvious that many factors must be considered in electing operative intervention and in choosing the procedure to be employed. The safest and most definitive procedure should be selected within the limitation imposed by circumstances.

Conclusions

Cholecystectomy is the safest and most definitive procedure in the majority of cases of acute cholecystitis. Although only a palliative procedure, cholecystostomy has definite value in the treatment of some patients with acute cholecystitis.

When performed for technical reasons or because of the presence of associated severe disease conditions, use of this operation does not indicate surgical timidity but good surgical judgment.

In the patient who is acutely ill with associated medical disease, planned cholecystostomy may be a lifesaving procedure if more definitive procedures cannot be accomplished expeditiously and in a technically satisfactory manner.

Unless contraindicated by other conditions, all patients who have had cholecystostomy should be considered for delayed elective cholecystectomy, since otherwise many will have subsequent difficulties.

Pliny's* Cure for Earache

For pains and diseases of the ears Pliny recommended using the urine of a wild boar, kept in a glass vessel, or the gall of a wild boar, swine, or ox, mixed with castor oil and oil of roses in equal proportions. The best remedy for earache, however, was the bull's gall, warmed with leek juice or with honey, and this was particularly effective if there was some suppuration.

For offensive exhalations from the ears, the bull's gall, warmed in a pomegranate rind, was considered to be very excellent. "Some persons are of the opinion that it is a good plan to wash the ears with this preparation in cases where the hearing is affected; while others again, after washing the ears with warm water, insert a mixture composed of the old slough** of a serpent and vinegar, wrapped up in a dossil of wool."

In all cases where there is any rupture of the ear drum, these preparations are used in combination with woman's milk.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 332)

A laparatomy with common bile-duct exploration revealed one single stone in the common bile duct, close to the ampulla. The common bile duct was thick and fibrotic, while the gallbladder was found to be small and atrophic, showing evidence of a previous inflammatory process. A cholecystectomy was done. Following surgical intervention the patient has had an uneventful postoperative recovery with clearing of his jaundice.

Report of Six Cases

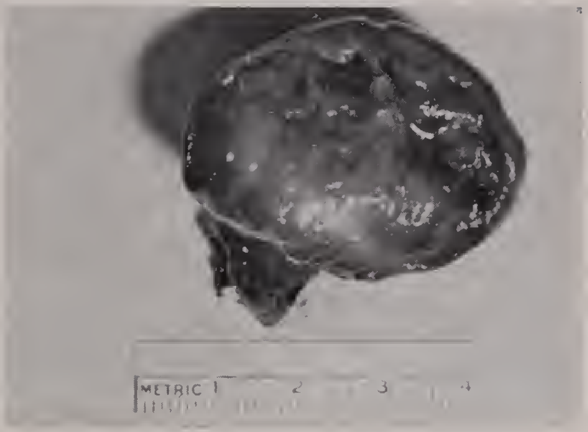

Fig. 5 — Polypoid adenoma of duodenum

Bleeding into the gastrointestinal tract continues to present a serious problem which taxes our resources in arriving at a correct diagnosis and in instituting proper treatment. In the majority of cases gastrointestinal hemorrhage is correctly attributed to lesions of the esophagus, stomach, duodenum, or colon, areas in which diagnostic procedures are accurate and fairly easily carried out. In a significant number of cases the site of the hemorrhage cannot be determined by the diagnostic methods now available.

Although it is generally stated that hemorrhage from the small bowel is uncommon, a careful consideration of this area as a source of bleeding will probably produce a better yield of bleeding lesions. There has been a tendency to neglect the jejunum and ileum in diagnostic considerations in determining the source of gastrointestinal bleeding. Diagnosis is difficult because of the length of the small bowel, its mobility, the elasticity of the bowel wall, and the relatively small size of the lesions.

From the records of a large hospital, embracing a forty-nine year period, Brief and Botsford[1] have recently reported a series of sixteen cases of major bleeding from the mesenteric parts of the small intestine. The lesions included eight neoplasms, three primary nonpeptic ulcers of the jejunum, and one case of each of the following: Meckel's diverticulum, diverticulosis, telangiectasis, blind-pouch syndrome, and granuloma secondary to Witzel's enterostomy. Although this small number of cases from this sophisticated center seems to indicate that primary bleeding from the small bowel is rare, I believe that this is misleading and that hemorrhagic lesions in the small bowel are more common than has been suspected.

During the past eight years, in a small hospital, I have observed and treated five patients who were bleeding from lesions of the mesenteric small bowel and one additional patient who had hemorrhage from a polyp of the duodenum. Hemorrhage, or related symptoms, such as anemia, inability to keep the blood at a satisfactory level, weakness, dyspnea, etc., were the major complaints. Not any of the patients had hematemesis, although it has been shown[2] that hematemesis can occur when the bleeding lesion is below the ligament of Treitz. Two of the patients were known to have duodenal ulcers; preoperatively it was thought that the bleeding originated in these ulcers.

In none of the patients was the source of the bleeding determined before operation. Two of the patients had been extensively studied in prominent medical centers where every diagnostic tool was available.

Adenomatous Polyp of Jejunum

A white female, age 43 years, was admitted to the hospital on May 12, 1958, because of weakness, anemia, and black stools of one week's duration. She had been weak and "all in" for a year. In 1955, when she had become weak and dyspneic, she was treated elsewhere with transfusions, but the source of the bleeding was not determined. Several episodes of gastrointestinal bleeding followed with similar inability to find the source.

Except for pallor, there were no significant findings on physical examination. The hemoglobin was 6.25 grams. An irritable duodenal cap was reported; otherwise, Roentgen studies of the stomach, small bowel, and colon were reported as negative.

At laparotomy, after a very careful search, a tumor was palpated in the upper portion of the jejunum. Through an incision in the bowel wall a polypoid tumor on a long pedicle was removed. Convalescence was uneventful and the patient has remained well.

The polyp measured 1.7 x 1.4 cm. Microscopically there was found a fibrous connective tissue core with large blood vessels covered with folded, normal-appearing intestinal mucosa.

Neurilemmoma of Jejunum

A white man, age 78 years, was admitted to the hospital on November 4, 1958, because of gastrointestinal hemorrhage, anemia, and weakness. During each of his four previous admissions with the same symptoms he was given transfusions and medical treatment. A duodenal ulcer had been found on X-ray examination. Operation had been suggested but not urged because of the patient's advanced age and obesity.

At operation on November 10, 1958, a deformity and scarring of the duodenum were found. At approximately twenty-four inches below the ligament of Treitz a tumor the size of a golf ball was discovered in the jejunum. The mesenteric lymph nodes were not enlarged. Following resection of the segment of bowel containing the tumor, convalescence was smooth and complete. The patient, now age 83 years, is well.

The specimen consisted of 15 cm. of the upper jejunum. In the mid-portion of the resected specimen, adjacent to the mesentery, there was a round, elevated mass covered with smooth serosa and measuring 3 x 3 x 2 cm. The mass protruding into the lumen of the bowel measured 2.5 x 2 x 1.5 cm., and was covered with flattened mucosa showing a small area of ulceration. Microscopically the tumor was composed of irregular, large and small bundles of cells with long, narrow nuclei tending to arrange themselves in palisades. There was no evidence of malignancy.

Carcinoid of the Ileum

A girl, age 18 years, was admitted to the hospital on March 19, 1955, because of bleeding from the bowel and weakness.

In 1951, at the age of 14 years, this patient had experienced her first gastrointestinal hemorrhage. In January, 1955, there was a second episode of bleeding, followed by a third in February, 1955. Many studies had failed to disclose the source of the blood loss.

At operation a carcinoid tumor was found in the ileum three inches proximal to the ileocecal valve. Three and six inches above this tumor there were smaller carcinoids. There was also glandular involvement. The segment of ileum containing these three lesions, with the adjacent gland-containing mesentery, was excised.

The specimen consisted of approximately 60 cm. of small bowel and mesentery. There were multiple carcinoids of the ileum with ulceration and with metastasis to the mesentery and a regional node.

Since her recovery from the operation this patient has had two children and has remained well.

This patient, 18 years of age, was younger than any reported by Moertel, Sauer, Dockerty, and Baggenstoss[3] in their series of 209 cases. They found the extremes of age to be 24 and 90 years. They noted a "striking tendency toward multicentricity of origin" of the carcinoid tumor, which was a feature of the case herein reported, and in only two cases was there ulceration of the mucosal covering. They stated that gastrointestinal bleeding was not common and usually occurred late in the course of the disease.

Hemangioma of the Ileum[4]

Known to have a duodenal ulcer and while under treatment for this ulcer, a white man of 50 years was admitted to the hospital on August 11, 1957, with bleeding from the gastrointestinal tract and with weakness and fainting. He was in mild shock. Hemoglobin was 9.45 grams and the hematocrit was 28. There was no vomiting.

When the bleeding did not cease, operation was performed on August 15. The stomach and upper small bowel were free of blood. In the mid-ileum there was an area in which the blood vessels beneath the serosa were dilated; there was also thickening of the bowel wall. This segment of bowel was resected and was found to contain a hemangioma from which the patient was bleeding. Recovery was prompt and permanent.

The presence of blood in the lumen of the bowel below the lesion and the absence of blood above the lesion were of great help in locating the origin of the hemorrhage.

Polyp of Duodenum

An elderly white male, age 79 years, had a hemorrhage from his intestine in the spring of 1962. During his hospitalization elsewhere he was given transfusions, and a diagnosis of duodenal ulcer was made.

In early December, 1962, the patient became weak and dyspneic. When he was found to be anemic he was again hospitalized, transfused, and studied; but his hemaglobin continued to fall.

On December 27, 1962, this patient was admitted to Naeve Hospital. He was well preserved and pale; his stool was black. The hemoglobin was 9.5 grams. Roentgenologic examination did not disclose the source of the bleeding. Normal value for hemoglobin was restored by transfusions, but it fell slowly and occult blood was present in the stools.

At exploration on January 16, 1963, examination of the stomach, duodenum, small bowel, and colon did not disclose any abnormalities. Cardiac arrest occurred during this exploration but normal sinus rhythm was promptly restored.

The duodenum was opened. In the retroperitoneal portion of the duodenum a tumor was palpated and subsequently delivered into the wound and removed. It measured 4 cm. in diameter; one surface was flattened and ulcerated. The stalk was 2 cm. in length and 1 cm. in diameter. The pathology report was ulcerated polypoid adenoma of Brunner's glands.

Unfortunately the patient remained drowsy following the operation and his temperature soared to 104°. He expired on January 18. Although permission for autopsy was not obtained, it was thought that he sustained cerebral damage during the cardiac arrest.

According to Charles, Kelley, and Campeti,[5] most primary duodenal tumors are benign and are located in the first portion of the duodenum, in contrast to the patient herein reported in whom the polypoid adenoma was in the third portion. Twenty-one of the thirty-one tumors reported by these authors were benign and only two, a cyst and a lymphangioma, were in the second portion of the duodenum. Only five of the patients had tumor bleeding.

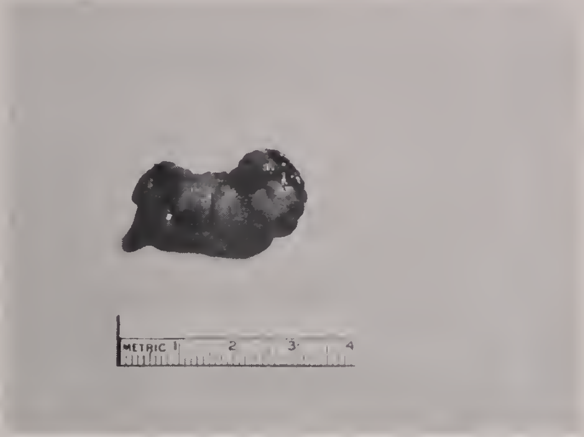

Fig. 6 — Polypoid leiomyoma of ileum

Polyp of Ileum (Leiomyoma)

A white man, age 47 years, gave a long history of intestinal hemorrhage which began in 1956 when he had his first hemorrhage. Examinations were negative. He remained well for two and one-half years.

In 1959 there was a severe hemorrhage which necessitated transfusions. Examinations were again negative. The patient was told that he had iron deficiency.

In 1960 there was another hemorrhage from the bowel and more transfusions. The bleeding was thought to be on the basis of capillary fragility.

From May, 1962, to March, 1963, this patient was in the hospital nine times and was transfused each time. He stated that he had spent more than four thousand dollars for medical expenses during this period.

On March 18, 1963, the stools became black and numerous, and the patient was admitted to Naeve

TABLE I

Hemorrhagic Lesions of Small Bowel

Lesion	Location	Age of Patient	Sex	Internal From First Symptom to Surgery	Result
1. Adenomatous Polyp	Jejunum	43	Fe	3 Years	Well
2. Neurilemoma	Jejunum	78	M	1 Year	Well
3. Carcinoid	Ileum	18	Fe	4 Years	Well
4. Hemangioma	Ileum	50	M	4 Days	Well
5. Adenomatous Polyp	Duodenum	79	M	9 Months	Died
6. Leiomyoma	Ileum	47	M	7 Years	Well

Hospital on March 19 in mild shock. Hemoglobin was 6.7 grams. Thirteen units of blood were administered during this hospitalization. Roentgenologic examination was again negative except for "spasm" of the duodenum.

At exploration on March 27, a polyp in the midileum was promptly found and removed. The tip of this polyp was 1.6 cm. in diameter, with ulceration of two thirds of its surface. The stalk was 2 cm. in length and 1.1 cm. in diameter. The pathologic diagnosis was ulcerated polyp, probably on the basis of a pedunculated leiomyoma.

Pfister and Tatarowicz[6] estimate that in fifteen per cent of cases of gastrointestinal hemorrhage the origin of the bleeding remains obscure. Retzloff, Hagedom, and Bartholomew[7] found that exploratory laparotomy in 100 cases of gastrointestinal hemorrhage of obscure origin revealed the site and cause of the hemorrhage in 30 patients, of whom 12 had lesions of the small bowel. If there is persistence or recurrence of the bleeding and its source eludes detection by available diagnostic procedures, laparotomy is indicated. This should consist of meticulous examination of the entire gastrointestinal tract with opening of the stomach or duodenum when necessary. After their discovery, small bowel lesions are usually not difficult to excise surgically.

Summary

In gastrointestinal hemorrhage of obscure origin, either gross or occult, consideration should be given to lesions of the small bowel. In most instances these lesions cannot be detected prior to exploratory laparotomy. Here presented are six cases of gastrointestinal hemorrhage from small bowel lesions, all of which were found at laparotomy and all amenable to surgical treatment. One elderly patient succumbed to cerebral damage caused by cardiac arrest; five patients are well.

Acute Emphysematous Cholecystitis[**]

ROBERT B. BENJAMIN, M.D.[*]
Minneapolis, Minnesota

ACUTE EMPHYSEMATOUS cholecystitis is an inflammation of the gallbladder associated with gas-forming organisms. Stoltz first reported gas in the gallbladder in 1901. His findings were on autopsy cases, and he thought the emphysema was a post-mortem occurrence.[1] Lobinger, in 1908, was the first to describe gas in the gallbladder at surgery.[2] VonFriedrich, in 1929, described the X-ray appearance of emphysematous cholecystitis, and Hegner, in 1931, made a preoperative diagnosis on the basis of the X-ray appearance of the gallbladder.[3] Although at least 105 cases have been reported in the medical literature, only seven of these were reported prior to 1940.[1,4]

Etiology

The etiologic mechanism of emphysematous cholecystitis is not completely understood. Just as in other cases of cholecystitis, there is an obstructive mechanism, usually a stone in the cystic duct. Over 50% of the patients give a past history of symptoms consistent with gallbladder disease.[5] About one-fourth of the patients with emphysematous cholecystitis are *diabetic.*[6] An interesting paradox is the fact that, whereas in all cases of cholecystitis, approximately 80% of the cases are females, in emphysematous cholecystitis the situation is reversed with approximately 83% of the cases occurring in men.[7] *This high incidence in males has never been explained.*

Organisms found in cases of emphysematous cholecystitis are all normal inhabitants of the gastrointestinal tract. *Clostridium welchii and Escherichia coli* have been cultured in 19 out of 50 gallbladders characterized by emphysematous cholecystitis.[7] Anaerobic streptococci and staphylococci are also cultured in some cases of this disease. It is interesting that these organisms are also commonly found in gallbladders submitted for pathologic examination in which there was no evidence of emphysematous cholecystitis.[8] Gordon-Taylor and Whitby found them in 19 out of 100 specimens submitted after surgery for chronic cholecystitis.[9] Markowitz has shown that even normal, healthy livers of adult dogs frequently harbor Clostridium welchii.[10] Andrews, Rewbridge, and Hrdina demonstrated that if the contents of the gallbladder of a dog were drained into its pelvis or thoracic cavity, severe gas gangrene developed. These authors concluded that there was a primary hepatitis with direct extension to the gallbladder. They demonstrated that the strains of

Clostridium welchii commonly isolated from the gallbladder of man at operations for cholecystitis and from the gallbladders of healthy dogs are of very low virulence as well as being non-spore-forming.[10]

It would seem that, in order for these gas-forming organisms of low virulence to grow, there must occur a markedly lowered resistance of the tissues. Gordon-Taylor and Whitby state that intestinal bacteria are the organisms most frequently found in gallbladder infections. They have noted that Clostridium welchii is usually associated with acute forms of cholecystitis. In nearly 9% of a series of gallbladders removed at surgery, they were able to isolate this organism and found it in the center of 13% of gallstones obtained in the post-mortem room. They concluded that the most reasonable anatomical explanation for infection of the gallbladder is the passage of intestinal bacteria via the portal system to the liver and then through the periportal lymphatics to the gallbladder. The observation of Andrews and his associates, that in acute cholecystitis that portion of the gallbladder adjacent to the liver is more edematous and thickened, would tend to support this theory.

Diagnosis

The diagnosis in emphysematous cholecystitis is dependent upon an X-ray picture of gas in the gallbladder (Fig. 1). One of the interesting phenomena seen in an X ray of an emphysematous gallbladder is a ring of gas surrounding the gas within the lumen of the gallbladder. This linear outline of gas surrounding the lumen of the gallbladder is apparently caused by perforation of gas through the mucosa into the submucosa where it dissects around between the submucosa and the muscularis of the gallbladder.[6] Following this, with increasing pressure, the gallbladder may rupture with the development of pericholecystic abscesses. Indeed, the presence of a pericholecystic abscess has been found in 71% of patients with emphysematous cholecystitis.[6]

Differential Diagnosis

Other than this fairly typical X-ray picture, the symptoms in acute emphysematous cholecystitis are quite typical of acute cholecystitis in general, being somewhat more acute and severe in nature. Having demonstrated gas in the gallbladder, there are four other conditions which might be considered:

1. An internal biliary fistula. In this condition gas is also seen in the biliary radicals, whereas this is not true in emphysematous cholecystitis. In addition there is no gas in the wall of the gallbladder in patients with an internal biliary fistula. Moreover, the communication with the gastrointestinal tract may be demonstrated in these patients by a barium meal or by barium enema examination.

2. Incompetence of the sphincter of Oddi may result in gas within the gallbladder, but the ducts will also contain gas.

3. Lipomatosis of the gallbladder. The radiolucency of lipomatous tissue may simulate gas in the gallbladder. However, there is no fluid level as there is in emphysematous cholecystitis and no change in the configuration of the translucent shadow with a change of position.

4. Gallstones may contain gas, but the X-ray picture is quite different from that of emphysematous cholecystitis. The gas in gallstones produces multiple stellate radiolucencies seen in the gallbladder area.[12]

The appearance of a severe fulminating case of cholecystitis in a male, especially if

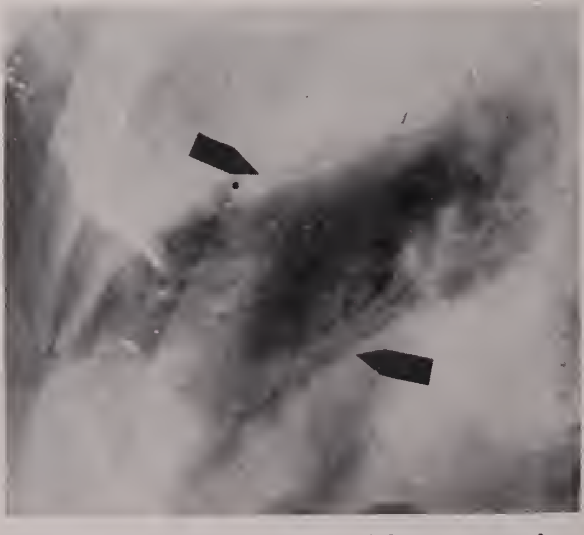

Fig. 1 — Roentgenogram of right upper quadrant of the abdomen in emphysematous cholecystitis. Arrows point to gas which has dissected around in a submucosal plane.

he is diabetic, should alert one to the possibility of acute emphysematous cholecystitis.

Treatment

There has been considerable controversy over the proper method of treating these patients. Earlier authors advocated conservative treatment, whereas recently there has been a tendency to prefer surgery, especially if the patient is seen early in the course of the disease.[5,13-15] The earlier reports demonstrated that conservative treatment carried less mortality, whereas later reports have indicated lesser mortality with surgical treatment. It is possible with antibiotic therapy to treat these patients conservatively, but the course is necessarily a long one. After subsidence of the process, the patient can be sent home and return for cholecystectomy approximately six weeks later. *However, if the patient is seen within three days of the onset of symptoms, almost all authors would prefer to treat the patient with cholecystectomy.*

Some have advocated treatment with gas-gangrene antitoxin, but no one has proved that this is of any benefit. Certainly many patients have been treated successfully without the utilization of gas-gangrene antitoxin.

Even if the patient is treated medically, the surgeon must be ready to operate at any time, as complications are frequent. The most common complications are rupture of the gallbladder and the development of pericholecystic abscesses or generalized peritonitis.

Case Report

A 76-year-old male diabetic entered the hospital on 12-10-58. His diabetes was of nine years' duration and was controlled with 20 units of N.P.H. and 40 units of regular insulin taken each morning. For three weeks he had had intermittent nausea, vomiting, and diarrhea. His condition had worsened considerably during the hours prior to admission. Abdominal pain had first been noted on the day of admission, and there was some radiation of this pain to the right scapular area. Physical examination revealed a pale, white male. There was tenderness in the right costovertebral angle, and the liver was palpable approximately two to three fingerbreadths below the costal margin. There was no abdominal tenderness, and normal bowel tones were present. A provisional diagnosis was made of diabetes mellitus with acidosis and impending coma, cholecystitis, and pyelitis. The patient was treated by vigorous control of his diabetes and parenteral administration of chloramphenicol. In addition, intravenous fluids were started. Penicillin, in dosages of 600,000 units I.M., was given every twelve hours.

Despite vigorous medical therapy the patient's condition worsened. An abdominal X ray taken on the sixth hospital day revealed gas in the gallbladder (Fig. 1). The following day, because of progressive deterioration in the patient's condition, surgery was performed. A gangrenous, emphysematous gallbladder was excised. A large pericholecystic abscess and considerable enlargement and scarring of the liver were noted. The entire upper portion of the abdomen had become walled off so as to form one huge abscess containing approximately one liter of green pus. Surprisingly, we could not culture any organisms from this pus. The wall of the gallbladder was crepitant and contained minute submucosal air bubbles two to three millimeters in diameter. The cystic duct contained several stones. The entire gallbladder floated when placed in formalin. Following surgery, the patient made an uneventful recovery and was discharged on the sixth postoperative day.

Summary

In this case, although surgery was not performed until seven days after the onset of abdominal pain and four weeks after the onset of vomiting and diarrhea, it appeared that without surgery the patient probably would have died.

Emphysematous cholecystitis should be considered whenever one is presented with a male patient who has symptoms of acute and fulminating cholecystitis, especially if diabetes is also present.

Although these patients can be treated medically, cholecystectomy is associated with lower mortality and morbidity.

If you have knowledge, let others light their candles at it. — Margaret Fuller

The Place of Jesus in the History of Medicine

IN TRACING the rise of modern medicine the figure of Jesus is given little if any place. The justification for this exclusion seems obvious. Jesus, it is argued, was involved in healings, but his healings were unrelated to the techniques of medicine. He was a miracle worker whose importance is to be evaluated from the standpoint of religion rather than of medicine. However, such a judgment overlooks important historical facts, because it starts from a misunderstanding of the factors giving rise to modern medicine, the development of which has generally been related to the application of the scientific method. Without the use of scientific techniques in the study of the natural world and supremely in the study of man the armamentarium of the modern physician against disease would be reduced to the vanishing point. The rise of science in western civilization since the Renaissance, and especially its refinements in the last century, have brought the treatment of illness to a level ot success unparalleled in the history of mankind. But to stop the investigation of modern medicine with this statement is to fail to ask a vital question. What were the roots of that attitude of concern for the ill person which made the search for cure such an all-consuming passion?

Modern medicine is an amalgam of scientific knowledge and concern for man's wholeness. Without both these factors the rise of modern medicine would have been impossible. It would be wrong to assume that there has always been an attitude of concern for the ill. Instead, they were often shunned by others and left to their own devices until they recovered or died. Unable to bear their share of work and responsibility they were despised as worthless. In the religions of antiquity the deity sought the pure and sound as his worshippers. The sick and sinful — these were often equated — were prey to the powers of darkness and hence allowed no place in the realm of the healthy. With the exception of the healing cult of Aesculapius, the dominant belief in antiquity was that the gods rejected the ill. When the sick person recovered wholeness of soul and body, then he would again be acceptable to the gods. Celsus, the Roman philosopher of the second century, gibed the Christians for the sheer irrationality of their religion because they did not shun but rather invited the sick in mind and body to their worship.

Such negative attitudes toward illness were also common among the ancient Jews. Although by the first century there had been some modification of the earlier Old Testament attitude toward illness, the dominant view persisted that illness was a divine judgment on sin. Hence to seek to heal disease was an act bordering on impiety. Some rabbinic teachers allowed the use of medicines, even while holding that illness was divine judgment. (*Mishna*, Berakhoth, 5:3). But such teachers tended to be the exception rather than the rule; they heralded a new outlook that was soon to dawn. Most men took the attitude of Job's friends Bildad, Zophar, and Eliphaz, who when they came to comfort him amidst his grief and acute illness, kept admonishing him to search his conscience for some unadmitted sin, for surely sin was at the root of his suffering. Although the book of Job sets out to refute this overly simple equation between sin and suffering, it was a critique little understood or accepted in its time. There was to be found in neither classical antiquity nor ancient Judaism that attitude of concern for man in illness and suffering which is a basic ingredient in the growth of modern medicine. The advent of an all-embracing concern for the sick was to await the rise of a new spiritual force in western civilization: a new force to be released through Jesus and his earliest followers.

The reason why worry kills more people than work is that more people worry than work. — Robert Frost

Painful Stump Neuroma

- Treatment
- of

HARRISON H. FARLEY, M.D.
Minneapolis, Minnesota

Tribute to Dr. Peyton

Dr. William Peyton served as Director of Neurosurgery at the University of Minnesota from July 1, 1940, to June 30, 1960. Following his retirement in 1960, he accepted the position of attending neurosurgeon at the Minneapolis General Hospital. This post he diligently served until his death on March 3, 1962.*

Dr. Peyton was the epitome of the ideal surgeon to the residents during that time. No calls to Dr. Peyton went unanswered. Willingly and with enthusiasm, he would return to the hospital at any hour of the night to patiently instruct and supervise the resident through a delicate neurosurgical procedure. He made regular ward teaching rounds during which he would spend a considerable amount of time defining not only procedures but the pathophysiological reasons for each procedure.

He also made many suggestions to those of us on the general surgical service, one of which was responsible for the successful outcome of the case presented in the following article. Dr. Peyton will be remembered and revered as a skillful surgeon, dedicated teacher, and valued friend.

Following division of a peripheral nerve during the course of an amputation, there is a subsequent enlargement of the cut end which consists of a branching mass of Schwann cells and proliferating axones. This is termed a neuroma and is usually nontender. However, on occasion, it will become quite sensitive and be the source of a great deal of consternation to the amputee. It is not known why these neuromas are sensitive in only a few cases; however, it is thought that a poorly healed stump with excessive scarring around the nerve ending will favor the development of such a problem.

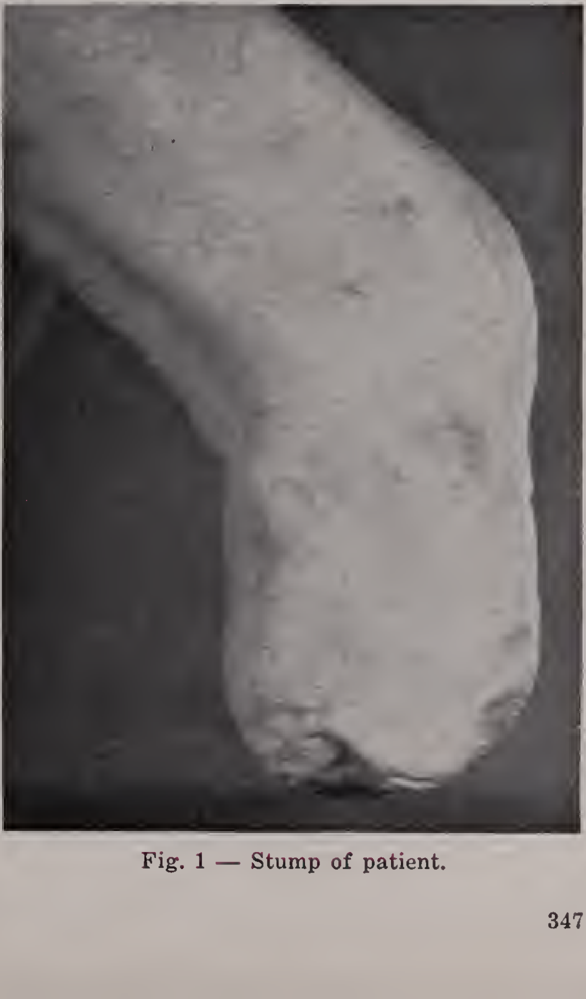

Fig. 1 — Stump of patient.

---

*(Since January 1, 1964, the Hennepin County General Hospital.)

The multiplicity of problems that may develop following an amputation was well brought out and studied by S. Weir Mitchell from his extensive experience during the American Civil War.[1] In his text he states that in his observations on the stumps he studied at the 400-bed hospital for nervous diseases at Philadelphia, neuromata developed at the transected ends of all the nerves.[2]

During the course of World War II, several large-scale conferences on the problems of amputees were held and it was the consensus of opinion that if a particularly tender area of the stump is involved and if this can be temporarily ameliorated by a direct injection of 1 percent Procaine, it is fairly certain that a painful neuroma exists. During the course of one of these conferences, it was pointed out that the following procedures should not be performed for a painful stump: 1) repeated resections of neuromas, 2) neurectomies of nerve trunks at higher levels, 3) reamputation, 4) periarterial sympathectomy, 5) intrathecal injection of alcohol, 6) posterior rhizotomy.[3]

For local burning pain and tenderness which are confined to the actual stump, they recommended: 1) chemical or surgical interruption of the regional sympathetics, 2) section of the spinothalamic tract, 3) single resection of neuroma if such is located.[4]

Leriche described transecting a painful nerve trunk with immediate suture to prevent neuroma formation without striking results.[5] Boldey recommended implantation of the transected nerve into a tunnel in adjacent bone to prevent neuroma formation.[6]

At the present time, from the experience gained from World War II, it is generally recommended that the proper method for dividing large nerves during clean amputations is to first draw them down slightly, cut across them cleanly, and allow them to retract. If a central vessel bleeds, it can be ligated with fine silk.

The treatment for painful neuromas, then, is by no means standardized. Once excised, they tend to recur and dissection through a well-healed stump may lead to other undesirable results (i.e., causalgia,* scarring).

The following case history is of interest because the patient fits well the category of recurrent painful stump neuroma and because a variation of Leriche's technique proposed by Dr. Peyton led to a most satisfactory result.

Case History

A 52-year-old male was admitted to Minneapolis General Hospital in January 1955 for treatment of ischemic signs and symptoms in his right leg. It was felt at that time that the arteriosclerotic occlusive disease in the vessels of the leg was too far advanced to lend itself to a reconstructive procedure but that a lumbar sympathectomy should be performed. This was accomplished, but in the subsequent postoperative weeks, there was a worsening of the ischemic changes and in late February 1955, a below the knee amputation was performed (Figure 1).

Approximately four months after this procedure, the patient noticed the gradual onset of pain in the amputation stump. He had previously noted phantom limb pain, but this was different in that there was point tenderness in one localized area of the stump. The pain did not abate, and in January of 1958 the stump site was revised and a neuroma of the tibial nerve was excised.

The patient was pain-free for a period of three to four months and then noticed the return of his old pain. He bore the distress for a period of a year but then came back for further help. At that time deep to the mid-portion of the scar and just behind and medial to the tibia was an area of extreme sensitivity. It was felt that this lay directly over the tibial nerve ending, and after noting the pain could temporarily be relieved by direct injection of 1% Procaine, surgery was again recommended.

At surgery, a neuroma, 2 cm. wide and 4 cm. long was carefully delineated from the surrounding scar tissue. Proximal to this, the nerve was of normal size. A complete transection through the nerve just proximal to the neuroma was made and carefully reconstructed with interrupted 5-0 silk sutures. Then, 1 cm. proximal to the sutured anastomosis, a second complete transection was made and this again sutured. A third transection was planned but not performed because of a problem with exposure. The neuroma was left undisturbed and the wound closed.

Following the operation, the patient noted complete relief of pain in the stump. He has been followed for five years, has remained pain free and uses his below-the-knee prosthesis with dexterity. There has been no recurrence of his previous symptoms during the four-year follow-up.

Discussion

Dr. Peyton felt that it was the snarl of regrowing axones that acted as the trigger mechanism for the pain. If three serial transections of the nerve were made, only a small number of axones would reach the final nerve ending because of the decreasing percentage that successfully bridge each anastomosis.

---

*See Test Your Word Score Page 359.

In the operation performed, it would not have been necessary to reopen the amputation site, and in fact, by so doing, the exposure was compromised and only two of the desired three transections were made. If the occasion should present itself in a different patient, an approach through the distal popliteal space would be used as diagrammed (Figure 2).

It is realized that a single successfully treated case certainly does not warrant the conclusion that all painful stump neuromas should be treated in this manner. Nevertheless, certain factors were present that made the case of definite interest: the fact that excision of the first painful neuroma failed with redevelopment of a second painful neuroma and because the second neuroma was left undisturbed in the stump. Dr. Peyton had used the procedure with success in several other patients.[7] Evaluation of a significant series of patients who have undergone this procedure at the University of Minnesota should help determine the ultimate merit of the procedure.[8]

Summary

A case of recurrent painful stump neuro-

IT'S THE LAW

Humiliation and Embarrassment are Elements of Damage

A doctor should have been required to produce at the trial of a malpractice suit against him by a patient a letter written by him to his insurance carrier, in which he made a detailed statement of his handling of the patient's case, where he waived the privileged nature of the letter by sending a copy to another doctor, a Texas intermediate appellate court ruled.

The doctor testified that he left only one gauze pack in the patient's vagina after an operation and gave instructions that it was to be removed by the nurse the next day. When he visited the patient the next day, the nurse's notes indicated that the pack had been removed. The doctor made no check to determine whether it had, in fact, been removed. The patient testified that she saw the nurse remove a gauze pack the day after the operation.

A few days later, after she had left the hospital and returned to her studies at a law school, a stench developed which was extremely embarrassing since most of the school's students were male. Two weeks after the operation the patient consulted another doctor, who removed a second gauze pack from her vagina.

There was evidence from which a jury could find that the doctor negligently left a gauze pack in the patient's vagina after the operation and that the negligence was the proximate cause of humiliation and embarrassment to the patient, the court said. The patient testified that she probably would not have brought suit if the stench had been her only cause for complaint. That testimony did not make the maxim *de minimis non curat lex* (the law does not concern itself with trifles) applicable, since humiliation and embarrassment are genuine elements of damage and, under the facts of the case, could not be held insignificant as a matter of law, the court ruled.

Dobbins v. Gardner, 377 S.W.2d 665 (Tex., March 19, 1964; rehearing denied, April 16, 1964)

Between the great things that we cannot do and the small things we will not do, the danger is that we shall do nothing. — Adolph Monod

The Doctor's Visit, Jan Steen 1626-1679, Mauritshuis, The Hague

In Diverticulosis and Diverticulitis...

METAMUCIL® brand of psyllium hydrophilic mucilloid

"**Diverticulosis** ... a low-roughage diet is advisable.... Constipation is avoided, preferably by the daily use of Metamucil.

"**Diverticulitis** Mild, chronic symptoms of diverticulitis, such as diarrhea or flatulence also are treated[1] by low-roughage diet, adequate fluid intake and Metamucil...."

Usual Adult Dosage: One rounded teaspoonful of Metamucil (or one packet of Instant Mix Metamucil) in a glass of cool liquid one to three times daily.

Metamucil is available as Metamucil powder in containers of 4, 8 and 16 ounces and as flavored Instant Mix Metamucil in cartons containing 16 and 30 single-dose packets.

Research in the Service of Medicine

*
She lost weight

*a result of
'METHEDRINE'® brand
METHAMPHETAMINE
HYDROCHLORIDE
therapy

Her once unruly appetite is now well tamed with 'Methedrine' (methamphetamine hydrochloride)...an easy way to help control food craving and "hunger pains."

Side effects: Insomnia may occur if taken later than 6 hours before retiring. The usual peripheral actions of sympathomimetic amines (vasoconstriction and acceleration of the heart) are minimal and little noticed on low or moderate dosage.

Complete literature available on request from Professional Services Dept. PML

Contraindications and precautions: Should not be used in patients with myocardial degeneration, coronary disease, marked hypertension, hyperthyroidism, insomnia or a sensitivity to ephedrine-like drugs. Moderate hypertension in the obese is not necessarily a contraindication since it may be relieved as the overweight is reduced.

'Methedrine' brand Methamphetamine Hydrochloride: Tablets–5 mg., scored, in bottles of 100 and 1000.

Mammography—A Screening Examination for Breast Cancer Detection?

PERFECTION OF a practical screening examination suitable for routine use in detecting early carcinoma of the breast is an eagerly sought-after goal. It is assumed that such an examination if applied on a wide scale would make earlier treatment possible for large numbers of patients and would lead to an eventual reduction in the mortality from this disease.

In the December issue* Gershon-Cohen and Pick* present a significant body of evidence supporting the use of mammography both as a routine screening examination for detection of preclinical cancer of the breast and as a means for more complete preoperative evaluation of patients with clinical breast disease. Their study demonstrates, as did a recent study from the Mayo Clinic, that in some cases carcinoma of the breast can be detected earlier by mammography than by physical examination alone. Gershon-Cohen and Pick have found 32 carcinomas in 30 patients among 1150 women given roentgenographic examinations of the breast at six-month intervals over an eight-year period. Thus 32 carcinomas have been detected in approximately 18,400 separate mammographic examinations, a detection rate of 1.7 carcinomas per 1000 examinations, closely paralleling the 1.6 carcinomas per 1000 examinations reported in the recent Mayo Clinic study.

The question then is not: Can preclinical carcinoma be detected by routine mammographic examinations done as a screening test? Rather one asks: Does the yield of carcinoma justify the effort, the expense, and the psychological impact of this examination if it is applied on a large scale? Obviously the answer depends to a great extent upon one's personal judgment. It appears to this observer that although mammography is of value in the study of high-risk patients such as those who already have had unilateral mastectomy for cancer, a yield of only 1.6 or 1.7 carcinomas per 1000 examinations is hardly adequate to justify recommendation of mammography as a routine examination in asymptomatic women. It seems that development of a practical screening examination must await either further refinement of this roentgenographic technic or the development of new technics which can detect, with accuracy, not only the earliest stages of invasive carcinoma of the breast but the in situ and premalignant stages as well.

**Depend on low-cost,
low-dosage Prolixin
— once-a-day**

Prolixin is a dependable tranquilizer that provides your patient with low cost therapy. No other tranquilizer costs less. Safe and convenient for office use—Prolixin in a single daily dose provides prolonged and sustained action. Markedly low in toxicity and virtually free from usual sedative effects —Prolixin is indicated for patients who must be alert. Clinical experience indicates fluphenazine hydrochloride is especially effective in controlling the symptoms of anxiety and tension complicating somatic disorders such as premenstrual tension, menopause, or hypertension—also useful for anxiety and tension due to environmental or emotional stress. When you prescribe Prolixin you offer your patient effective tranquilization that is low in cost, low in dosage and low in sedative activity.

THE SQUIBB TRANQUILIZER

WHEN TRANQUILIZATION WITHOUT SEDATION IS DESIRABLE, TRY

PROLIXIN®

SQUIBB FLUPHENAZINE HYDROCHLORIDE

SIDE EFFECTS, PRECAUTIONS, CONTRAINDICATIONS: As used for anxiety and tension, side effects are unlikely. Reversible extrapyramidal reactions may develop occasionally. In higher doses for psychotic disorders, patients may experience excessive drowsiness, visual blurring, dizziness, insomnia (rare), allergic skin reactions, nausea, anorexia, salivation, edema, perspiration, dry mouth, polyuria, hypotension. Jaundice has been exceedingly rare. Photo-sensitivity has not been reported. Blood dyscrasias occur with phenothiazines; routine blood counts are recommended. If symptoms of upper respiratory infection occur, discontinue the drug and institute appropriate treatment. Do not use epinephrine for hypotension which may appear in patients on large doses undergoing surgery. Effects of atropine may be potentiated. Do not use with high doses of hypnotics or in patients with subcortical brain damage. Use cautiously in convulsive disorders.

AVAILABLE: 1 mg. tablets. Bottles of 50 and 500.

Coccidioidomycosis—It Can Happen Here

Lest we fall into the error of thinking that this disease occurs only "way out there in the Southwest," attention is called to the interesting article on coccidioidomycosis in Minnesota by Strom, Hall, and Casey in the November issue of MINNESOTA MEDICINE.* It is true that the disease occurs only in those persons who have lived in or have visited the endemic areas, but this bit of travel information may not be disclosed unless the patient is questioned directly. With the increasing mobility of our population, more and more persons who live outside the endemic areas are acquiring coccidioidomycosis every year. These patients are apt to overlook the mild initial phase of the illness and later fail to associate it with eventualities when the disease again overtakes them long after their return to nonendemic regions.

A number of important factors must be kept in mind in dealing with suspected cases of fungus disease. It is not necessary for a person to remain in endemic areas for a long time in order to acquire infection with Coccidioides immitis. There is a need to suspect fungus infections in cases of obscure illness, especially of the lungs. There are few clinical findings characteristic of the fungus diseases that help to distinguish them, and pulmonary roentgenographic shadows are not specific. The diagnosis is, therefore, dependent on laboratory procedures; and except for recovery of the organism by culture, other methods leave much to be desired. The coccidioidin skin test is sometimes negative in the presence of active disease. Thus, a negative result does not rule out the possibility that the disease is present. Serologic tests are not universally available, are difficult to perform and standardize, are transitory in nature when positive, require serial examinations to be conclusive, and are subject to cross-reactions with other organisms. Sometimes, however, they are helpful and quite conclusive in making a diagnosis when cultures fail. Histologically, the infection is characterized usually by a caseous granuloma; however, this lesion is not diagnostic of coccidioidomycosis unless the organism can be positively identified in the tissue. The most reliable method of diagnosis, therefore, is culture of the organism.

Our attention has been so concentrated on the lung lesions of coccidioidomycosis that we are apt to overlook the disease in other organs, particularly the central nervous system. A history of the patient's having traveled to the endemic areas in the Southwest should always be considered important information, as it may lead to the correct diagnosis of an obscure illness.

The Parnate-Specific Patient

The return of the antidepressant drug, Parnate (tranylcypromine — SK&F), will be welcomed by the medical profession. When Parnate was suddenly withdrawn last winter, many patients being maintained on it suffered a relapse or worsening of symptoms. Most physicians have at least a few "Parnate-specific" patients: persons who respond favorably to this compound but fail on other types of treatment. Many of these patients, after years of disability and therapeutic failure, showed striking improvement a few days after Parnate therapy was begun. Most such patients need maintenance therapy over long periods or perhaps indefi-

nitely if they are to retain their improvement. Clear-cut Parnate responders are not common, but they do occur in significant numbers. For example, in a recent survey, 55 Minnesota psychiatrists recalled 603 such Parnate-specific cases during the three years when the drug was available. The occurrence of these definite and often dramatic therapeutic results has been one of the chief factors accounting for the intense interest shown in this compound. Letters by hundreds of physicians from all parts of the country appear to have been a factor in leading the FDA to conclude that the drug was not expendable and that its benefits were worth the risk.

Parnate will be re-introduced with revised prescribing directions which contain a refreshing comment regarding the high incidence of placebo response and spontaneous improvement in depressed patients. The new labeling, in addition, contains a number of restrictions and precautions which, if followed, should lessen the frequency and severity of adverse reactions. Also, the fact that the drug was withdrawn from the market and the publicity subsequent to this should make physician and patient alike aware of the hazards involved.

A major difficulty encountered, even with the new labeling, concerns the definition of that patient most likely to respond favorably to Parnate. Listing "severe mental depression" as the chief indication for Parnate, the revised prescribing directions go on to state that Parnate may aggravate co-existing agitation and anxiety. In actual practice, however, many types of patients respond to this agent. While usually an element of depression or withdrawal may be found, Parnate-specific cases occur among some schizophrenics, especially catatonics, some chronic neurotic patients with anxiety, and mildly-depressed but fearful and anxious patients. Many of these, however, would not fit in under the heading of "severe depression," as recommended in the revised prescribing directions.

Admittedly, the identification of the potential Parnate-responder is a difficult task, as reliable predicters are lacking for all psychotropic drugs. Physicians may get some help from the formal diagnosis and from target symptoms, but all too often they must fall back on trial and error. We suspect that there is some type of biochemical or physiological difference between those who respond to MAO inhibitors, such as Parnate, and those who do not. Since clinical symptoms do not differentiate these two groups, we badly need a test, possibly a physiological one, which would have predictive value. Let us hope that research will soon provide the answer.

Diet and Cholesterol

Two SCHOOLS of thought, if not more, are apparent in most areas of medicine. The one under consideration has led to an excellent cartoon with the caption, "Are you a cholesterol-is-all doctor or a cholesterol-is-all-nonsense doctor?" As time goes on and more data become available, evidence is favoring an intermediate position — as is often the case. Data from the large, long-term, prospective epidemiologic study in Framingham have indicated, with little doubt, that there is a direct relationship between the level of blood cholesterol and the incidence of coronary heart disease in men aged 30 to 59 years and women aged 40 to 49 years. Furthermore, as might be anticipated from experience in other areas of medicine, there is no sharp cut-off point or "normal limit," but rather an increase in incidence of coronary heart disease with increasing levels of cholesterol from less than 200 mg. per 100 ml. to those in excess of 260 mg. per 100 ml. The morbidity ratio from coronary heart disease in men aged 30 to 49 years in the latter group is

Smith Kline & French Laboratories SK&F

more than fivefold that in the former. The factors influencing the level of blood cholesterol, although not all clearly understood, do include hereditary as well as dietary factors. Unfortunately, there is still no evidence to establish firmly that lowering the level of blood cholesterol by any means presently available will prevent, arrest, or reverse coronary or peripheral atherosclerosis.

Despite these shortcomings, continued careful research on the causation and control of elevated levels of blood cholesterol in humans is needed.

The interesting observations made by Dr. Herbert W. Johnson during medical mission service in Tanganyika, reported in the November issue of MINNESOTA MEDICINE,* suggest a relationship between saturated fat in the diet and the level of blood cholesterol in an ethnic subgroup not previously studied. Although the relatively small number of samples and the wide range of values for cholesterol do not permit firm conclusions, the data presented do add support to the concept that the dietary intake of saturated fat is an important factor as it relates to the level of cholesterol in the blood. Research currently in progress may answer the all-important question: Will a decrease in the dietary intake of saturated fat have a beneficial effect on the incidence of coronary heart disease?

The Editor's Soliloquy

Mob Psychology

In adopting Medicare, are we not capitulating to mob psychology in our eagerness to find a solution for a few minor ills: crashing through a jungle instead of charting a course? The voice of mob psychology is not the aggregate of individual voices; it is an irrational, ephemeral, pernicious phenomenon which might for the moment seem to constitute consensus, but is nevertheless no valid index of social enlightenment or progress. This voice can define conservatism as extremism and can promulgate a casual off-the-cuff remark as documentary evidence. It can compel us to adopt laws, practices, ventures, attitudes that in our saner moments we would never have considered, which may require years to transcend. It can produce an evil image, unjustified and unjustifiable, which cannot be erased.

It is safe to say that the American Medical Association and all physicians are eager to provide hospital and medical service to and for all people; but we cannot envision lasting benefits from a plan that has been devolved from the hysteria of mass neurosis and political expediency.

Carl O. Rice, M.D.

President's Letter Continued from Page 307.

American Medical Association supports the fullest implementation of the Kerr-Mills Bill enacted into law in 1960. This law revised existing provisions for federal participation in old-age assistance programs and established a new federal grant-in-aid to assist states in the payment of health services for those more than 65 years old who require financial aid only for health care. Complete and unlimited care is possible through this mechanism. The law permits the individual states wide latitude in creating a program to meet the needs of their medically indigent. The American Medical Association has recommended that eligibility for such care be simply and easily determined, outside the mechanism of the welfare services, and that administration be carried out under some other department of the government than the welfare department. Physicians in Minnesota should inform themselves about the provisions of the Kerr-Mills Law and Minnesota Medical Assistance for the Aged, so that they can answer questions raised by their patients or the public.

In subsequent letters I shall discuss the actions taken by the House of Delegates of the American Medical Association at the special session of the delegates, and some of the plans which have been suggested by groups of physicians in Minnesota and elsewhere.

"Let us therefore brace ourselves to our duties and so bear ourselves that, if the British Empire and its commonwealth last for a thousand years, men will say: "This was their finest hour." — Winston S. Churchill — Speech in the House of Commons, June 18, 1940 — the day of the French capitulation.

MILTRATE®

meprobamate 200 mg. + pentaerythritol tetranitrate 10 mg.

Long-acting coronary vasodilation plus effective tranquilization for prophylaxis of pain in angina pectoris

---

Indications: 'Miltrate' is useful for prophylaxis of pain in angina pectoris, especially where accompanied or intensified by anxiety. **Contraindications:** Like all nitrates, pentaerythritol tetranitrate should be avoided or prescribed cautiously for patients with glaucoma. Previous allergic or idiosyncratic reactions to meprobamate contraindicate subsequent use. **Precautions:** *Meprobamate* —Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies. **Side effects:** Side effects of 'Miltrate' administration have been few, consisting of headache, nausea, sleepiness and insomnia, and dizziness. *Pentaerythritol tetranitrate*—The most common side effects are transient headache, nausea, and rash. Weakness, palpitation, flushing, gastrointestinal distress, and lightheadedness have been reported on a few occasions. *Meprobamate*—Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse. **Dosage:** Usual dosage is one or two tablets before meals and at bedtime. Individualization of dosage is required for maximum therapeutic effect. Doses above 12 tablets daily are not recommended. (Note: When titration of the doses of the individual components of 'Miltrate' is desired, meprobamate is available as 'Miltown' [meprobamate] tablets and 'Meprospan' [meprobamate, sustained release] capsules.) **Supplied:** White tablets, each containing meprobamate 200 mg. and pentaerythritol tetranitrate 10 mg. ***Before prescribing, consult package circular.***

Curbstone Consultation

Cystinuria

QUESTION: I would like to know something concerning future management for a patient of mine with a diagnosis of cystinuria and recurrent cystine stone formation. What measures can I employ, if any, to discourage the formation of these stones?

ANSWER: Cystinuria represents an inborn error of metabolism. In this disease there is increased excretion of the amino acids, cystine, arginine, ornithine and lysine. In the kidney each competes against the others for a common tubular reabsorptive mechanism. Though excretion of one of the other amino acids may exceed that of cystine, the cystine stones form because of their limited solubility. Although the cystine stones are more insoluble in acid then alkaline urine, alkalinizing the urine is generally not utilized in the programs of management for these patients because of the rather small increase in solubility of such stones that follow even large increases in the pH of the urine. Principal management, therefore, centers around maintaining large urinary outputs to provide a volume sufficient to hold the cystine in solution. The efficacy of restricting foods in the diet rich in methionine and cysteine (which are converted to cystine) is not well established.

Myocarditis and Measles

QUESTION: How frequently is myocarditis encountered as a complication of measles? Is the pathogenesis of the myocardial changes due to a direct invasion of the myocardium by the virus?

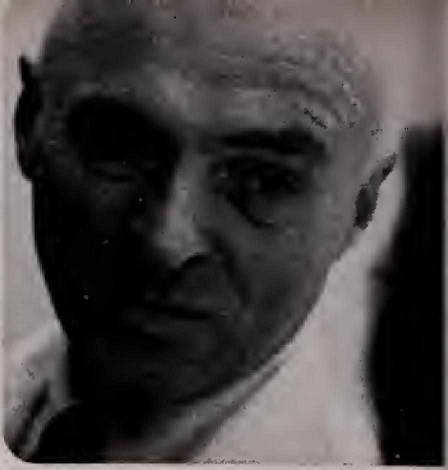
ANSWER: Measles myocarditis is a rarely reported complication. However, among fetal cases of measles it may be found at autopsy in up to four per cent of the cases. In one study concerned with a determination of the incidence of measles myocarditis among cases of myocarditis in acute infectious diseases in children, about two per cent resulted from measles, and in all such cases the complication of severe bronchopneumonia existed.

In this condition direct invasion of the myocardium by the virus has been incriminated, as well as vasculitis, tissue anoxia, and circulating toxins. It presently remains in doubt as to which view is correct.

Don't hesitate to be as revolutionary as science. Don't hesitate to be as reactionary as the multiplication table. — Calvin Coolidge

Buy you a cup of coffee?

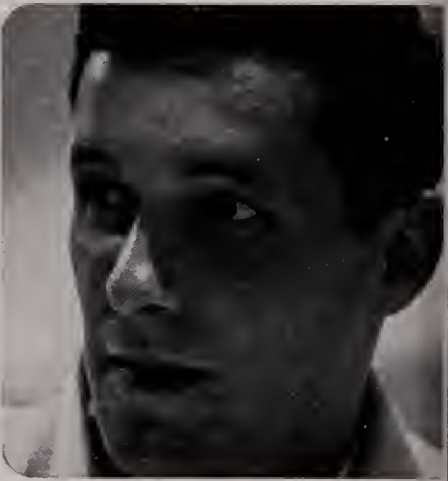
Fine! This last patient...



Mrs. Jones?

Yes, sir. She's down to 140/85.

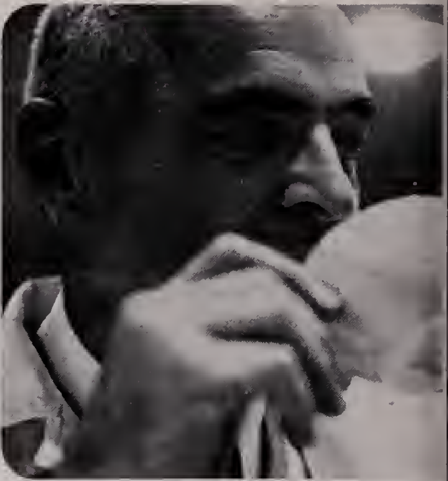
Right. When we started, she was 195/120.



Is that Regroton again?

I use it for all my hypertensives.

Does Regroton always work this well?



Not always. But the exception prove the rule.

Composition: Each tablet contains chlorthalidone, 50 mg., and reserpine, 0.25 mg.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: Discontinue 2 weeks before general anesthesia, 1 week before electroshock therapy, and if depression or peptic ulcer occurs.
Precautions: Reduce dosage of concomitant antihypertensive agents by one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take particular care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side Effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.

Availability: Bottles of 100 and 1000 tablets.
Average Dosage: One tablet daily with breakfast.

Fracture–Trauma Conference

The Limping Young Teenager

Slipped Upper Femoral Epiphysis

Early diagnosis of slipped upper femoral epiphysis may result in treatment preventing permanent disability of the hip.

The entity is primarily an idiopathic disorder of the epiphyseal line of the femur adjacent to the head. As a result of a widened, softened, and weakened line, the head displaces posteriorly and in varus from its usual relationship with the neck of the femur.

Acute Slip

Most dramatic is the acute, total displacement traumatically without antecedent symptoms. This individual is between twelve and sixteen. His examination is similar to the older individual with fractured neck of the femur with displacement. Recognition of hip disorder is easy and X ray confirms the diagnosis (Fig. 1). Urgent reduction and internal fixation are indicated. Some cases will eventuate in arthrosis secondary to vascular loss. Delay in treatment increases incidence of avascular necrosis of the head.

Chronic Slip

Onset is so subtle that the individual cannot accurately recall the duration. More deceiving are the symptoms. They do not lead the patient or examiner to the hip in a large number of cases. Distress appears centered on the thigh or toward the knee. A limp may be noted by the teenager's friends or parents long before the patient has admitted symptoms. Frequently, the limp and distress may disappear for a few weeks at a time. Disability is increased in subsequent attacks.

In the full syndrome, the patient may have some distress in the groin. Characteristically, he walks with a limp, the hip and knee flexed. The whole extremity is in external rotation from the hip. Passive motion of the hip may be one-half or one-third of normal. Greatest loss is of internal rotation. There is atrophy of the thigh musculature. Didactically, the patient has been described as the Froelich-type fat boy, but slip can occur in any body build prior to fusion of the epiphyseal line.

Continued

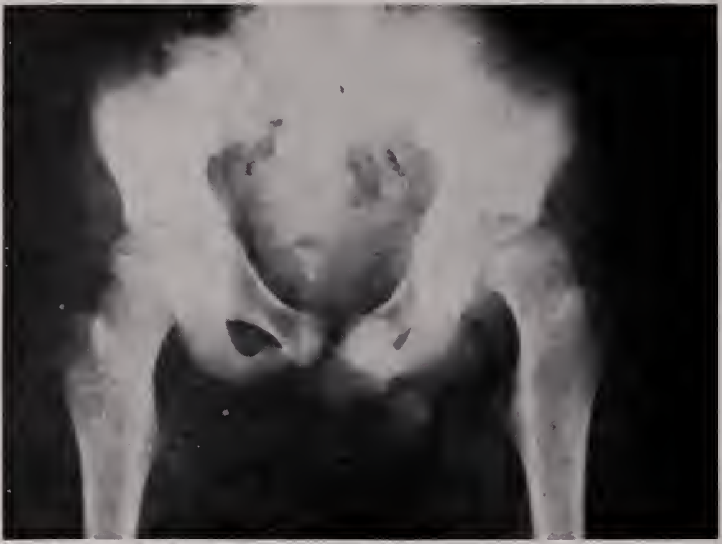

Fig. 1 — Acute slipped upper femoral epiphysis, left.

X ray in the Chronic Slip

There is slow progression from normal position of the head to gross displacement. All individuals suspected of hip trouble should have two views of the hips. The first is an anteroposterior view of the pelvis, the common view, and the most frequently misinterpreted. Widening and irregularity of the epiphyseal line unilaterally are noted. The head may not have shifted enough to alter the normal head and neck relationship.

Diagnostic from the beginning are lateral X rays of the hips taken with the legs in the frog-leg position (Fig. 2). The widened epiphyseal line may be seen, but slipping of the head posteriorly is readily determined (Fig. 3).

Progression of symptoms is associated with further slipping, with varus easily recognizable on the anteroposterior view of the pelvis. A lateral X ray will show posterior angulation of the axis of the head on the axis of the neck up to 60° or 70°. The bone of the superior portion of the neck tends to round off. The inferior neck seems to thicken and drift along with the displacing head.

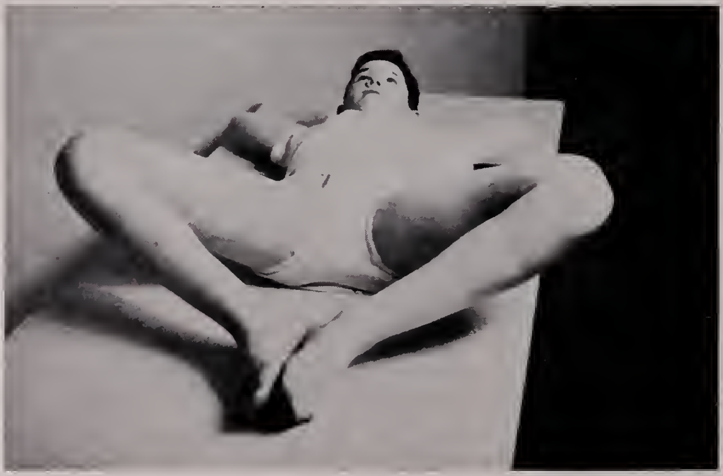

Fig. 2 — Position for frog-leg X ray of pelvis.

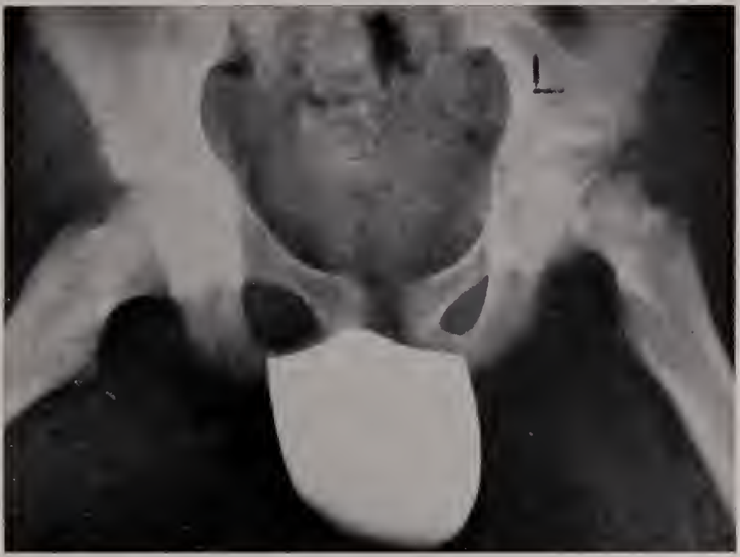

Fig. 3. — Chronic slipped upper femoral epiphysis, left.

Treatment in the Chronic Slip

Urgent care is recommended in all cases hoping to prevent the complete slip and its serious consequences. In-situ fixation with pins, screws, or threaded wires is performed in those cases having less than thirty degrees change in the axis of the head and neck. This may be expressed as the head being off less than one-third of its diameter. The outlook in these cases is good. Full weight-bearing is permitted in three months.

Guarded prognosis is given when the head is displaced more than thirty degrees or more than one-third of its diameter. In-situ nailing may lead to early arthrosis because of malalignment of the head and acetabulum and the loss of normal internal rotation of the hip.

When the line is wide and appears nonossified, gentle but firm manipulation on the fracture table preoperatively may reduce the displacement to a degree where pin fixation in the new position is indicated (Fig. 4). One can expect a percentage of these cases to have avascular necrosis of the head, but this percentage should be smaller than in cases having open cervical osteotomy.

The major slip may be treated by open replacement after osteotomy through the epiphyseal line. Upward to forty percent of these cases have vascular changes in the head leading to arthrosis.

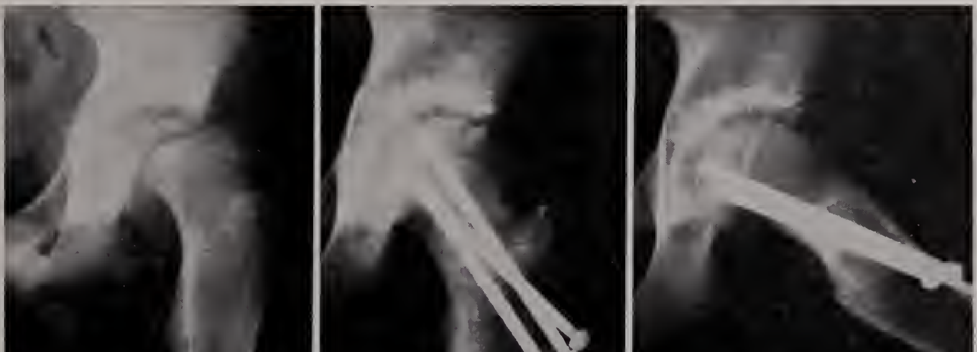

Fig. 4 — Method of internal fixation by Knowles' pins.

Continued

Certain cases with severe slip have been treated by in-situ nailing of the head, and internal rotation osteotomy of the upper femoral intertrochanteric area. This remote osteotomy is an attempt to avoid avascular necrosis.

Treatment in Late Cases (Epiphyseal Line Closed)

This is the only group in which surgery is not urgent. Treatment is directed toward reduction or prevention of arthrosis. Cervical or trochanteric osteotomy may be indicated. Spontaneous ankylosis in untreated cases, or arthrosis following surgery may be treated by cup arthroplasty or, more rarely, prosthetic replacement.

This Series 1953 to 1963

Seventeen individuals comprise this series. Their ages at the time of operation were between 10 and 16 years. Five cases had acute total slips of the epiphysis treated by immediate operation and fixation with Knowles pins. In this group, one patient had a moderate necrosis with no change in the joint line. This individual may develop an early osteoarthritis. The other case of necrosis was associated with some hypertrophic lipping at the junction of the slipped epiphysis. There was minimal limitation of motion in this hip. Thus, two out of five hips were complicated by avascular necrosis.

Fourteen hips were involved with a slow slip. Five of these were nailed in situ without manipulation. Four in-situ nailings resulted in excellent function clinically and by X ray. One in-situ nailing was more than one-third off but shows a good result. Five slow-slipping epiphyses were treated by manipulation, improvement in position, and fixation with Knowles pins. So far no necrosis has been noted in these ten cases of slow slip.

In one severe slow slip, cervical osteotomy was done with good functional result but obvious necrosis of the head with alteration of the femoral head and neck.

Two individuals with more than one-third slip were treated by in-situ fixation of the femoral head and neck and subtrochanteric osteotomy held by Jewett nails. The osteotomy was to correct varus and external rotation deformity.

One bilateral case was recognized only five years after acute slip when checked on an Army examination. The untreated hip had slipped considerably into varus and posteriorly, but the patient insisted that he had never had symptoms. This followed an original total slip on the right which had been fixed by Knowles pins. At that time the hip X rays were normal on the left side. The patient was emphatic about total absence of symptoms in the left hip, though it had slipped about 40 to 50 per cent.

Bilateral cases were 17.5 per cent or the reported average. Only two cases of the 17 were girls.

Conclusion

Early recognition of slipped upper femoral epiphysis may be expected through suspicion, examination, and especially frog-leg lateral hip X rays. Early treatment by in-situ internal fixation in a slip of less than one-third can lead to excellent lifelong results. Prognosis after slip of more than one-third the diameter of the head must be guarded no matter how skillfully surgery is executed. Delay, traction, or casts are to be avoided because the displacement can increase or become complete, thereby leading to poor results. Arthrosis and even ankylosis may result in untreated cases. As the other hip may become involved, the physician, patient, and family should be alert to any complaint. The individual is not free from hazard until the epiphyseal line is closed.

A busy practitioner may see only one or two cases in a lifetime. Early recognition and treatment can prevent a crippling hip disorder.

Oral Surgery on President Cleveland in 1893

(As Narrated by W. W. Keen)

Doctor Hasbrouck first extracted the two left upper bicuspid teeth (very badly ulcerated) under nitrous oxide. Doctor Bryant then made the necessary incisions in the roof of the mouth, also under nitrous oxide.

At one-fourteen P.M. ether was given by Doctor O'Reilly. During the entire operation Doctor Janeway kept close watch upon the pulse and general condition. Doctor Bryant performed the operation, assisted by myself and Doctor Erdmann.

The entire left upper jaw was removed from the first bicuspid tooth to just beyond the last molar, and nearly up to the middle line. The floor of the orbit — the cavity containing the eyeball — was not removed, as it had not been attacked. A small portion of the soft palate was removed. This extensive operation was decided upon because we found that the antrum — the large hollow cavity in the upper jaw — was partly filled by a gelatinous mass, evidently a sarcoma. This diagnosis was later confirmed by Dr. William H. Welch, of the Johns Hopkins Hospital, who had also examined the former specimens.

The entire operation was done within the mouth, without any external incision, by means of a cheek retractor, the most useful instrument I have ever seen for such an operation, which I had brought back with me from Paris in 1866. The retention of the floor of the orbit prevented any displacement of the eyeball. This normal appearance of the eye, the normal voice, and especially the absence of any external scar, greatly aided in keeping the operation an entire secret.

Only one blood vessel was tied. Pressure, hot water, and at one point the galvanocautery, checked the bleeding. The hemorrhage was not large, probably about six ounces — say, a tumblerful — in all. At the close of the operation, at one-fifty P.M., the pulse was only eighty. The large cavity was packed with gauze to arrest the subsequent moderate oozing of blood. At two-fifty-five P.M. a hypodermic of one-sixth of a grain of morphine was given — the only narcotic administered at any time.

What a sigh of intense relief we surgeons breathed when the patient was once more safe in bed can hardly be imagined![*]

In Chronic Illness: B and C vitamins are therapy

An imbalance of water-soluble vitamins and chronic illness often go hand in hand. STRESSCAPS, containing therapeutic quantities of vitamins B and C, is formulated to meet the increased metabolic demands of patients with physiologic stress. In chronic illness, as with many stress conditions, STRESSCAPS vitamins are therapy.

STRESSCAPS® FOR PROFESSIONAL RECOMMENDATION ONLY

Stress Formula Vitamins Lederle

Each capsule contains:

Vitamin B_1 (Thiamine Mononitrate)	10 mg.
Vitamin B_2 (Riboflavin)	10 mg.
Niacinamide	100 mg.
Vitamin C (Ascorbic Acid)	300 mg.
Vitamin B_6 (Pyridoxine HCl)	2 mg.
Vitamin B_{12} Crystalline	4 mcgm.
Calcium Pantothenate	20 mg.

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

Retroperitoneal Fibrosis Simulating Carcinoma of the Pancreas

Report of A Surgically Treated Case Complicated by Fatal Postoperative Hemorrhage

Retroperitoneal fibrosis is itself an uncommon disease and documented involvement of the pancreas by this process is extremely rare. The following case is presented because of the unusual manifestations of the disease and because of a fatal complication from the operation utilized to treat it.

Case Report

A 73-year-old white male was admitted to Ancker Hospital on September 30, 1963, with a history of progressive numbness and weakness of his extremities for over a year. In 1954 a posterior fossa astrocytoma had been removed.

Physical Findings

Pertinent physical findings at time of admission were confined to the nervous system and included marked loss of deep sensation and moderate peripheral and distal muscle weakness, greater on the right than on the left. Moderate hypesthesia and hypalgesia,* most marked on the right leg, truncal ataxia and mild bilateral cerebellar signs were present. There was no jaundice, dark urine or light stools.

Laboratory Findings

Laboratory findings included a hemoglobin of 12.6 gm. per 100 ml., a white blood count of 8,550 per cu. mm. with a normal differential, and a normal urinalysis. Lumbar puncture: cerebrospinal-fluid pressure-180 mm. water, 20 lymphocytes/cu. mm., sugar 65 mg.% and protein 58 mgm.%. Skull roentgenograms showed no change in the appearance of postoperative defects noted on previous roentgenograms or in the position of metal clips. Diagnoses of recurrent cerebellar tumor or peripheral neuropathy were considered. There was no definite evidence to support the former diagnosis. A radioactive brain scan was negative. As part of the investigation an upper gastrointestinal roentgenographic study demonstrated a persistent narrowing in the region of the gastric antrum. Gastroscopy disclosed what appeared to be a fungating mucosal lesion in the distal portion of the stomach.

Findings at Operation

At laparotomy on December 16, 1963, a stony hard mass measuring 4 cm. in greatest dimension was seen evolving from the head of the pancreas to deform the antrum. This mass was adherent to surrounding structures including the inferior vena cava. The

---

*See Test Your Word Score Page 359.

Continued

common bile duct was moderately dilated. Although the mass simulated a carcinoma of the head of the pancreas, multiple biopsies from the periphery of the mass submitted for frozen sectioning were reported as being comprised of dense fibrous tissue negative for carcinoma. Because the organ appeared grossly involved by a malignancy, a pancreatoduodenal resection was carried out. The pancreas was anastomosed to the jejunum by invagination of the cut end into the open end of the jejunum. An end-to-side choledochojejunostomy and posterior gastrojejunostomy completed the repair.

Pathologic Findings

Histology of the mass in the head of the pancreas showed no neoplasia. Instead, there was dense fibrosis with an occasional focal aggregate of lymphocytes and a few scattered ones (Figure 1). Also, a few variable-sized nerve trunks were encompassed by the fibrous mass. The tissue diagnosis was that of a localized mass of pancreatic fibrosis with evidence of minimal chronic inflammation.

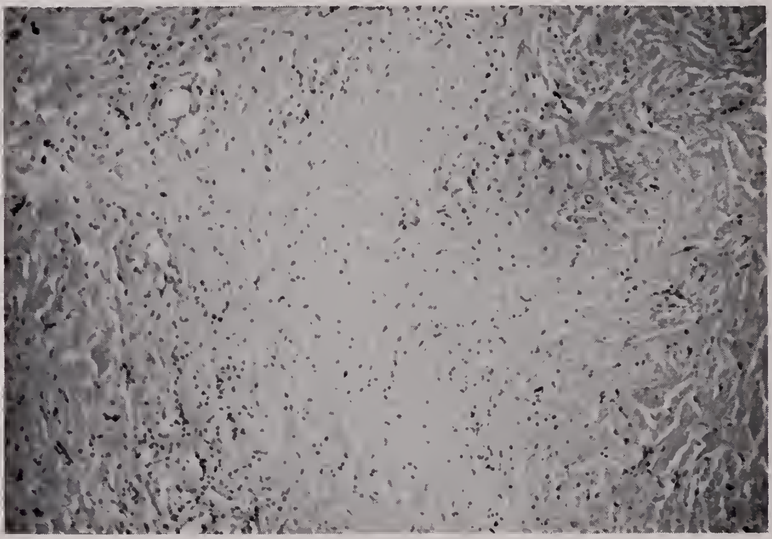

Fig. 1 — Photomicrograph showing dense collagenous fibrous tissue and scattered lymphocytes. (Hematoxylin and eosin x 100).

Postoperative Course

The patient's postoperative course was uneventful until two days postoperatively when the abdominal incision began to drain a small amount of serosanguinous fluid. The wound was explored under local anesthesia and disclosed a broken figure of eight-wire suture in the fascial closure. This was replaced. Following this the patient gradually improved and progressed in a satisfactory manner until December 27, 1963, when an anemia of 9.1 gm.% hemoglobin was noted. Two units of whole blood were given. On January 14, 1964, the patient developed massive gastrointestinal bleeding which failed to respond to transfusion and nonoperative measures. At operation a gastrotomy demonstrated profuse bleeding originating in the proximal loop. This loop was opened in the region of the pancreatojejunal anastomosis, and the bleeding was seen to originate in a large ulcerated area in the end of the pancreas at the point where this organ had been invaginated into the jejunum. The bleeding was controlled with considerable difficulty by oversewing the ulcerated area. The patient's postoperative condition was unsatisfactory and he died a few hours later.

At autopsy the pancreatojejunal anastomosis showed digestion of pancreatic substance and small bowel mucosa as well. A branch of the splenic artery had projected into the ulcerated area and had been tied with a silk suture. Splenic infarction had occurred secondary to inadvertent ligation of the splenic vein by another suture which had been placed in an attempt to control the bleeding. The inferior vena cava was surrounded but not invaded by a fibrous mass which had a similar appearance to that of the mass in the previously excised segment of pancreas. There was no evidence of classical retroperitoneal fibrosis in the region of sacrum. The ureters were of normal calibre and free of obstruction. There was nothing to suggest a sclerosing cholangitis. The brain showed dilated lateral ventricles, more marked on the left, and prominent narrowing of the white matter of the cerebral hemispheres, again more marked on the left. There was also slight dilatation of the third ventricle. An additional finding was that of a small hemorrhage into the base of the left side of the pons. The cerebellar hemispheres were free of recurrent tumor.

Discussion

Although Albarron is credited with the first description of retroperitoneal fibrosis in 1905,[1] Ormond's[2] report in 1948 of two patients with involvement of the ureters established this condition as a clinical entity. This latter study was the stimulus for the subsequent recognition and reporting on many patients. Most of these reports have appeared in the urological literature, because ureteral obstruction by the fibrous mass has been the common manifestation of the disease.

Involvement of the biliary tract and pancreas by retroperitoneal fibrosis is a less frequent manifestation. Whether primary sclerosing cholangitis is the same disease or a variation of it has not been settled. Schwartz and Dale[3] reviewed 13 cases of primary sclerosing cholangitis and added six of their own. In some patients the entire area of the extrahepatic biliary tree was encompassed in dense adhesions. Usually, however, there was diffuse thickening of the walls of the extrahepatic biliary tract with encroachment upon the lumen. The duct system was completely involved or the hepatic ducts spared and the disease restricted to the length of the common duct. Bartholomew and associates[4] have documented the apparent progression of sclerosing cholangitis to typical retroperitoneal fibrosis in one patient.

We have been able to find only one other patient with involvement of the pancreas by retroperitoneal fibrosis where this lesion was grossly indistinguishable from carcinoma of the pancreas.[4] Cameron and associates,[5] Raper,[6] and Schneider,[7] have described patients with retroperitoneal fibrosis, whose pancreas as well as other retroperitoneal structures were involved in the diffuse fibrous mass.

The fatal bleeding which occurred in this case would appear to be a complication of the end-to-end pancreatojejunostomy[8] rather than of the disease. At the Mayo Clinic Monge and associates[9] discussed their experience with 65 patients who had undergone pancreatoduodenal resection from carcinoma of the periampullary region from 1949 through 1955 and discovered that the most common method of reconstruction was end-to-end pancreatojejunostomy with end-to-side choledochojejunostomy and distal polya gastrojejunostomy. Four of their five patients with postoperative gastrointestinal bleeding died. These authors caution that the greatest postoperative danger is from autodigestion of tissues near the pancreatojejunal stoma with resultant bleeding. This complication accounted for half of the surgical deaths in their series. Massive bleeding in the case report described herein was the result of digestion and ulceration of pancreatic substance exposed in the jejunal lumen at the end-to-end pancreatojejunal anastomosis. This is an intrinsic defect in this type of union of the pancreas to the small intestine and, in the authors' opinion, contraindicates its use. It is apparent that once the complication of bleeding from

Continued

this site developed, only total removal of the remaining pancreas could permanently control the bleeding. Unfortunately this was not done. End-to-side pancreatojejunostomy with careful approximation of pancreatic duct to jejunal mucosa and buttressing of the end of the pancreas with the serosa of the jejunum is a much safer anastomosis. If the pancreatic duct is small, the anastomosis can be made over a stent which will pass into the intestine in a few days.

Summary

A patient with retroperitoneal fibrosis grossly indistinguishable from carcinoma of the pancreas, who was treated by radical pancreatoduodenectomy, is described. Postoperative bleeding resulted from erosion of the pancreas exposed in the jejunal lumen. In light of this complication this type of anastomosis should not be utilized for reconstruction following pancreatoduodenal resection.

Neuro-Pediatrics Conference

Mental Retardation and Hearing Loss*

A six-and-one-half-year-old white female was referred to the University of Minnesota Hospitals on August 18, 1964, for evaluation of speech abnormality and possible mental retardation. The child had been treated several times for recurrent upper respiratory infections and otitis media. She is a mouth-breather, and the question of hearing-speech defect was raised by the parents. Neither mental nor emotional problems are apparent within the family. Because of the disturbing influence upon the family of pressure from neighbors and due to parental concern, Dr. Wm. Rice** recommended speech and hearing evaluation. He feels that the mother has been the most noticeable of the patient's problems; however, he feels she is quite mature and understanding of the situation.

Mr. Martin Kammermeier***

Examination in February, 1963, revealed that the child's speech was almost unintelligible, and because of her short attention span and hyperactivity, it was impossible to administer formal tests of articulation. Hearing tests were not given because of her extreme hyperactivity. She was able to repeat most sounds correctly, and examination results of her speech mechanisms were normal. She was observed to be a mouth-breather and to have a "chronic mild cold."

Psychological testing at St. Cloud State Teachers' College revealed an I.Q. of 77 on a Stanford-Binet test. Trial speech therapy under an advanced therapist was given from July 17 through August 17, 1963. There was no improvement in her speech, and the only progress made was that "she did not whisper as much."

Dr. James Zeese†

The child is a product of a full-term pregnancy and normal delivery. Her growth and development have been normal except that she did not walk until eighteen months. Toilet training was accomplished at two years of age and presented no difficulties. Her early speech development appeared

Continued

normal; as an infant she babbled, cooed and generally vocalized like any other child. She used single words at two years, and a combination of words shortly thereafter. It was not until the child was four years old that the mother became aware that her little girl was not as intelligible as other children. At this age, she would satisfy her wants by a minimum of vocalization accompanied by appropriate gestures.

At age five the child had measles with no sequelae. The father states that she is very clumsy and unco-ordinated, with a short attention span. There is no history of convulsion, head trauma, or other neurological symptoms.

Family history shows that the parents are both living and in good health, as well as three siblings. One of the mother's first cousins died of muscular dystrophy in the teens, and another is mentally retarded, presumably from birth injury.

Physical examination showed a hyperactive six-year-old female with a short attention span. At times she appeared to lip read and respond to normal vocal commands, but in an inconsistent manner. There was moderate tonsilar and adenoidal hypertrophy. The tympanic membranes showed scarring, but no perforations or fluid was seen.

Laboratory studies revealed the skull films to be normal except for a small calvarium. Urinary screening tests for metabolic defects were all negative.

Dr. William Rice*

The child has had several bouts of otitis media but has never been observed to have fluid behind the tympanic membrane. She had a perforation of one ear in the early part of 1963, and was evaluated by an otolaryngologist in St. Cloud who found no abnormalities at that time.

Dr. Frank Wright**

The main findings are her short attention span, clumsiness, and small head size of 49 cm. There is mild inco-ordination and dysmetria,† indicating some cerebellar disorder, though her stereognosis appears normal. This child represents a mild form of cerebellar dysfunction and intellectual retardation. If a hearing defect is present, it has not been sufficient to explain the picture of mental retardation. An electroencephalogram is not indicated, as there is no history of seizure disorder. In general, electroencephalography in the diagnosis of mental retardation is not particularly helpful, as one third of the children who are mentally retarded have normal electroencephalograms.[1] The small head size probably indicates lack of brain growth and has some correlation with intelligence; however, there is no definitive data on this point. In an anatomical and functional sense, there is a reciprocal relationship between cerebellum and motor cortex for controlling and modulating motor activity.[2] For instance, in children who have cerebellar deficit due to anoxia at birth, cerebellar symptoms generally improve with time, resulting from compensatory mechanism of the cerebral cortex.

In the past, some physicians have felt that hyperactivity was a seizure manifestation,[3] but anticonvulsant drugs have no effect on hyperactivity.

In this child the lack of paroxysmal activity and presentation of consciousness mitigates against diagnosis of convulsive disorder. However, the child could benefit from a trial dose of desoxyn to decrease hyperactivity. In some children with hyperactivity, amphetamine compounds seem to have a paradoxical effect; this can only be judged by a trial use of the drug.

**Pediatric Neurologist.

†See Test Your Word Score Page 359.

Dr. Harold Ireton*

On the Stanford-Binet test the child scored 87, indicating her ability within the dull normal range. Her concept of the human figure as measured by her ability to draw a man is average for her age. The mother's report of her general social maturity also indicates an average development in most areas as measured by the Vineland Social Maturity Scale. However, in the area of communication, the mother's report indicates difficulty in graphic representation; her printing is limited to copying and she demonstrates no writing whatsoever.

The above results for intelligence may be functionally too high, as other reports indicate that the child is hyperactive and has easy distractibility. In the testing situation, she was given every legitimate opportunity to perform up to the limit of her ability, as extraneous noise and distracting stimuli were at a minimum. The combined findings of intelligence which approaches the normal range, and the behavior manifestations of hyperactivity, distractibility and excitability, plus the reported motor incoordination suggest that we are dealing with a brain-injured child rather than a mentally deficient one. It would appear quite unlikely that she could perform adequately in a standard classroom situation. It should not be presumed, however, that since her measured I.Q. is misleadingly high and she functions at a lower level, this indicates a poor prognosis for future mental development. Her prognosis is somewhat uncertain, but she has shown apparent advance in the level of intellectual functioning, since her earlier intelligence evaluation, and she displays a friendly, outgoing personality, which should be an aid to her general adjustment.

In evaluating the parents, they both appear reasonably mature in their attitudes toward their child and in recognition of her difficulties. It was felt that the father may have more difficulty in accepting the possibility of a handicapped child and may need some counseling. A joint interview with the parents, including the psychologist, pediatrician and referring physician should be arranged to explore with them the details of the psychological testing.

Dr. Wentworth Quast*

It would be extremely important to know how the child is functioning at the present time in the first grade, as this may give us a better indication of her functioning intelligence. Special classes, particularly a smaller class, would certainly be indicated in the educational environment.

Dr. Frank Lassmann**

A 30-decibel bilateral conductive hearing loss is evident at all frequencies. The function of the sensori-neural (cochlea and 8th nerve) portion of the auditory system was judged to be normal as manifested by a normal response to bone-conducted stimuli. When words were made comfortably loud, she was able to understand and repeat them readily, suggesting a promising

Continued

candidacy for hearing-aid amplification or medical/surgical procedures.

Auditory memory span was a shade low, but still measured within the normal range. Vocabulary understanding, measured by a multiple-choice picture identification test, was found to be within her age group (another indirect verification of conductive rather than sensori-neural type of hearing impairment). Voice pitch, voice quality, and loudness were normal. Vowel and diphthong speech sounds were intact, but a number of soft consonant sounds were distorted, especially in final position and when blended with other consonants in pairs. This speech-precision finding was entirely in keeping with the limitations imposed by her hearing problem, but she remained very understandable. Oral speech mechanism was found to be normal with adequate tongue and jaw mobility, adequate diadochokinetic movement in articulators, adequate tongue size and extension forward and side-to-side. The most notable feature of the examination of the mouth was the presence of very large tonsils which raised the question of normal Eustachian tube function. There were no aphasia-type language aberrations.

Examination by an otolaryngologist is recommended for evaluation of the possible need for adenoidectomy and tonsillectomy as well as the possibility of reconstructive surgery of the middle-ear ossicular mechanism, if active middle-ear disease is found to be absent. Otosclerosis is unusual in such a young child and there is no family history of this disease. A primary question would be when such reconstruction, if any, should be attempted.

If surgery is postponed or not indicated and a tonsillectomy produces no appreciable change in her hearing, use of a hearing aid would be immediately recommended. At school, she should be given advantageous seating and placed in a small class in order to function more effectively. Her progress should be watched by the teacher and the speech correctionist.

The Final Recommendations of the Conference are as Follows:

1. Dr. Rice, her family physician, will maintain the primary role in further follow-up and counseling.
2. Recommendation will be made for special classes, preferably in a small group.
3. An otological examination will be obtained at the University of Minnesota Hospitals, and if it is decided that surgery should be postponed, Mr. Martin Kammermeier will arrange for the hearing-aid fitting and adjustment. The possibility of adenoidectomy and tonsillectomy will be discussed if there is found to be fluid in the middle ear.

Infections of the Urinary Tract

Part III — Symptomatology*

WILLIAM J. MARTIN, M.D.**
RICHARD D. WAGONER, M.D.**
Rochester, Minnesota

SYMPTOMS OF infection of the urinary tract are variable and depend largely on (1) the acuity of the process, (2) the bacteria's virulence, (3) the urinary and general resistance of the host, and (4) the presence or absence of underlying uropathy or predisposing disease.

Range of Clinical Manifestations

Manifestations of infection of the urinary tract may be minimal, as in asymptomatic bacteriuria, or they may appear as a fulminating systemic reaction with or without localizing signs. About half of the patients with chronic infections are relatively asymptomatic. Some persistent infections of the urinary tract are associated with antimicrobial-resistant bacteria, but the problem often occurs in patients in whom organisms remain responsive to drugs. This suggests either that the urinary tract is being recurrently contaminated or that there are nidi of bacteria which are not being reached by sufficient concentrations of the drug to ensure their eradication. Pyelonephritis can progressively destroy renal tissue while remaining asymptomatic. An explanation given is that small regions of infection in the kidney, having become localized by surrounding fibrous tissue or cellular reaction, can progressively destroy adjacent nephrons without being large enough to produce fever, pain, leukocytosis, or other manifestations. Another factor may be the persistence of bacteria in pyelonephritic lesions in transitional forms. Persistence of bacteria as transitional forms might explain progression of the disease despite sterile cultures of urine and biopsy specimens when standard media are employed. However, reinfection due to a new strain of organism probably occurs more frequently than relapse of an original infection.

In general, the shorter the duration of the disease, the greater is the likelihood of urinary symptoms. Infections manifested by chills, fever, and toxemia usually are associated with dysuria or pain and tenderness in the flank, directing attention to the urinary tract. However, about 10 per cent of patients with acute infection and systemic reaction lack such urinary symptoms. In the absence of localized signs, it is not uncommon to consider such an infection as a fever of undetermined origin; in patients with such fever, it is worthwhile to investigate the urinary tract for infection as well as for hypernephroma.

Urinary Frequency and Infrequency

While polyuria and frequency of urination usually are considered indicative of urinary infection, infrequent voiding may be the initial manifestation of an obstructive lesion of the lower urinary tract or of a functional obstruction such as a neurogenic bladder, which may be associated with or complicated by urinary infection. Also, although enuresis

**Section of Medicine, Mayo Clinic and Mayo Foundation.

frequently is of functional origin, it may be a manifestation of various organic conditions, including such infectious states as chronic pyelonephritis, tuberculosis, and postinfectious contraction of the bladder.

Diagnostic Dilemmas

Acute infections in the renal pelvis may rarely produce erosion into a blood vessel and thereby gross hematuria, which can cause confusion with tumors or cysts when associated with defects on urograms.

The distribution of the dermatomes from which the kidney's innervation originates is in the lower part of the abdomen; therefore nausea, vomiting, reflex ileus, and pain due to such infectious lesions as a septic renal infarct or abscess can be confused with various bowel syndromes. Cortical abscesses on the ventral aspect of the kidneys can both simulate and, by rupture, cause peritonitis. Infections in the right kidney can simulate appendicitis; conversely, retrocecal appendicitis with adherence to the right ureter can cause unilateral right pyelonephritis. Especially in older patients, infections of the left kidney may be confused with diverticulitis coli.

An abdominal mass, especially in a child, demands urologic investigation, since as many as 50 per cent of these masses in children originate from the genitourinary system. The mass may not be associated with symptoms or other clinical signs that identify its origin; if evidences of urinary infection are detected, the infection may be of considerable diagnostic value. The most frequent cause of such an abdominal mass in a child is said to be congenital hydronephrosis, followed closely in frequency by Wilms' tumor.[5] When bilateral abdominal masses are palpable, polycystic renal disease is first suspected. Because an ectopic kidney is occasionally confused with an abdominal mass of another cause, it is important to identify the renal parenchyma before considering more heroic investigation. In many cases, roentgenographic visualization of the urinary tract greatly aids in the determination of the type and location of abdominal masses. In certain cases of urinary infection, contradistinctly, excretory urography may reveal lateral deviation of the ureters indicative of an underlying retroperitoneal lymphoma or other tumor that may not be palpable clinically.

Infection as Causative Factor

Chronic infection of the urinary tract may masquerade as another entity. This possibility should be considered in so-called essential hypertension. The exact interplay of infection, renal potassium loss (or retention of sodium), and hypertension is not known; perhaps any one of them can initiate the others, thus establishing a vicious circle.

Renal disease is said to account for a higher percentage of cases of hypertension in children than in adults.[5] Therefore, hypertension in a child particularly dictates the need for a complete urinary investigation, including pertinent microbiologic procedures. In a patient who is more than 30 years old, the blood pressure is said to be significantly higher in bacteriuric than in nonbacteriuric patients.[1]

Although, as previously noted, the relationship of pyelonephritis to hypertension is controversial, the reported occasional favorable response of hypertension, especially of recent onset, to therapy of the pyelonephritis should encourage search for the disease. It is said that hypertension secondary to pyelonephritis eventuates in uremia or strokes more often, and in congestive heart failure less often than do other forms of hypertension. However, Schreiner[10] noted that congestive heart failure due to intervening hypertension was the presenting syndrome in a number of his patients with chronic pyelonephritis. In some patients, chronic urinary infection may present as malignant hypertension or as encephalopathy with convulsions and rising diastolic pressures, especially when they suffer an acute exacerbation of the infection. Healed and low-grade smoldering types of infection also may produce hypertension. If the process is inactive when the hypertension is discovered, the true nature of the problem may be apparent only to the pathologist.

However, in some patients with hypertension and urinary infection, the infection exists as a secondary phenomenon. If asymptomatic bacteriuria is a relatively latent stage in the natural history of pyelonephritis, long-term studies on the results of eliminating bacteriuria may aid in clarifying its relationship to hypertensive and other diseases.

In such syndromes as uremia of obscure origin, "salt-losing nephritis," and toxemia of pregnancy, the possibility of an underlying chronic infection of the urinary tract should be considered. Jackson[11] stated that pyelonephritis may be the most common cause of uremia. Some investigators believe that chronic pyelonephritis is the most common cause of "salt-losing nephritis." Urinary infections should be considered as possibly causative in suspected cases of toxemia of pregnancy, particularly when proteinuria, pyuria, and hypertension persist for seven days post partum. Asymptomatic bacteriuria is probably associated with an increased incidence of toxemia of pregnancy, but whether its detection and treatment reduce the risk of the complication is unclear. The prematurity and mortality rates for infants born to untreated bacteriuric patients are said to be higher than those for infants whose mothers are nonbacteriuric or have been treated for bacteriuria;[1] but this is disputable.

Infection as Complicating Factor

Since urinary calculi predispose to infection and since one of the ultimate phases of healing in infection of the urinary tract may be nephrocalcinosis, calcification is suggestive of infection. As previously noted, infection of the urinary tract should be considered a complication in certain other underlying abnormalities of the urinary tract or of the host. In this regard, idiopathic retroperitoneal fibrosis (fibrosing retroperitonitis), which is a more recently described entity that usually occurs in men in their early forties, obstructs the lower third of the ureters and is frequently complicated by urinary infections. Lateral deviation of the ureters on excretory urography is suggestive of an underlying retroperitoneal tumor such as a lymphoma, and medial displacement is suggestive of retroperitoneal fibrosis.

Urinary infections in diabetics, especially if oliguria occurs, should bring necrotizing papillitis to mind. Necrotizing papillitis, or so-called renal medullary necrosis, which may accompany chronic pyelonephritis and probably is a consequence of it, occurs much more frequently in diabetics than in nondiabetics. The complication also appears to have been precipitated in such susceptible persons by instrumentation of the urinary tract. The classic description of necrotizing papillitis includes a dramatic picture of sepsis, fever, lumbar pain, massive pyuria, microhematuria, culture of mixed organisms from the urine, uremia, and death. Also, in a classic instance, tissue from the papillae may be found by straining the urine with cheesecloth. However, some patients with necrotizing papillitis have died after a nondescript clinical course, usually in uremia. Bacteremia due to gram-negative bacilli sometimes occurs as a terminal event in these patients.

When certain states such as pregnancy, diabetes, disease or injury of the spinal cord, pelvic relaxation, and prostatism are encountered, urinary infections are likely, since statistically the probability is high and some of these infections are relatively asymptomatic. Although the phenomenon is not as common as it was previously in patients with chronic urinary infection, the physician should beware of possible underlying tuberculosis, especially if the patient has the disease elsewhere; the same applies to brucellosis. Secondary bacterial infection is even more confusing in patients with primary renal disease such as nephrosis or glomerulonephritis.

Other Causes of Urinary Symptoms

Burning sensation on micturition does not always indicate infection. Interstitial cystitis, urethral caruncle, and senile vaginitis may produce dysuria that is not due to urinary infection. Dysuria that continues despite control of infection does not warrant further use of antibacterial agents; use of any of several "bladder sedatives," such as phenylazo-diamino-pyridine hydrochloride (Pyridium) in amounts of 0.1 gm. four times daily, may be helpful, but local treatment of

Continued

the bladder may be necessary. Psychogenic frequency in a patient who recently has had acute infection of the urinary tract can also be confusing.

Less Characteristic Findings

In acute infection of the urinary tract, there are usually no signs of impaired renal function or hypertension such as sometimes occur in acute glomerulonephritis. Hematuria is not characteristic of pyelonephritis and calculus, and tumor and other lesions are considered first. Proteinuria of more than 3 gm. per day is not characteristic of infection and is more suggestive of glomerulonephritis. In urine of low specific gravity, detection of so-called gitter cells suggests pyelonephritis, but such cells are also found in other renal diseases. Some investigators believe that leukocyte casts in the urine sediment are indicative of pyelonephritis.

In certain diabetics, pyelonephritis might directly or indirectly contribute to a decrease in insulin requirements, which may be somewhat surprising since infection often exerts a contrary effect. A theoretic mechanism for decreased insulin requirements in patients with renal disease is one in which the renal parenchyma has a major part in the degradation of insulin; hence a destructive process of any type might cause a corresponding decrease in insulin requirements. Also any debilitating disease, including pyelonephritis, might reduce intake of food sufficiently to result in a decrease in insulin requirements.

Common Indices

The most commonly employed indices of urinary infection are (1) demonstration of persistent bacteriuria, (2) compatible findings on renal function studies, (3) corroborative cystoscopic, pyelographic, and other urologic studies, and (4) positive microbiologic and histologic data on renal biopsy. The degree of renal damage caused by urinary infection usually parallels the duration of the infection rather than the severity of the symptoms. Concentration of urine and results of renal clearance tests help to establish the degree of renal parenchymal damage. If, after fluids are withheld overnight, the specific gravity of the urine is 1.020 or more in the morning, renal function probably is not severely compromised. It appears definite that patients with asymptomatic bacteriuria have an increased incidence of impaired ability to concentrate the urine, elevated levels of blood urea nitrogen, and radiologically demonstrable lesions of the urinary tract. The most common method of testing for vesicoureteral reflux is to fill the bladder with a radiopaque medium, such as 6 per cent sodium iodide, through a small rubber catheter and obtain roentgenograms while the patient is voiding. Numerous refinements of the test are being explored.

Synopsis

Presented synoptically, investigation of the urinary tract, including pertinent microbiologic procedures, should be considered when there is no other apparent explanation for such symptoms and signs as loss of weight, anemia, persistent nausea and vomiting, hypertension, and fever. Atypical abdominal pains, abdominal masses of indeterminate nature, and certain predisposing conditions such as disease or injury of the spinal cord, underlying uropathy, pregnancy, and diabetes mellitus are among the clinical problems that also may prompt consideration of such evaluation.

Infection secondary to stones, strictures, cysts, tumors, and the like may have value as a diagnostic feature of uropathy. Premature intensive use of antibacterial agents without investigation in such cases may eventuate in a diagnostic loss.

Progress Note

No Bad Habits: When the patient was asked about his drinking habits, he said, "I never touch a drop of liquor. One quart of brandy lasts all week."

Grand Rounds

Renovascular Hypertension*

The majority of patients suffering from elevation of blood pressure are classified as having what is clinically designated as "essential or idiopathic hypertension." The pathophysiology of this type of hypertension is still a matter of dispute.

Extensive investigations have been undertaken in an attempt to clarify the role of the kidney in the pathogenesis of hypertension, and its ability to affect the peripheral resistance. It is our purpose to briefly review the experimental and clinical aspects of hypertension related to the abnormalities of the renal arteries and kidneys.

The Experimental Aspect of Renovascular Hypertension

The most potent stimulus to the study of hypertension came in 1934, when Goldblatt[1] reported his success in producing hypertension by constricting the renal arteries in dogs. Later he emphasized the many similarities which existed between the chronic and malignant renal hypertension in the dog, and essential and malignant hypertension in humans. The mechanism responsible for the development of experimental renal hypertension is at present unknown. Among the more important theories in this respect are: neurogenic, endocrine, and renal humoral mechanisms.

Most of the recent contributions have dealt with the humoral mechanism, about which the following three distinct views have been postulated: increased production of pressor amines normally metabolized by the kidney but now retained; absence of a renal substance which normally prevents hypertension; and production and liberation into the blood stream of a pressor substance which normally is either absent or not present in sufficient quantities to cause hypertension. Most of the experimental evidence presented to date favors the last view. The latter two hypotheses, however, have led to the classification of renal prival hypertension and renovascular hypertension.

---

*From the Department of Surgery, Mount Sinai Hospital, Chicago, Illinois.

Continued

Renal Prival Hypertension

Grollman[2] studied bilaterally nephrectomized rats and, upon obtaining hypertension, theorized that the kidney is the source of the blood-pressure regulative mechanism which prevents hypertension in normal animals. The same phenomenon was demonstrated in bilaterally nephrectomized dogs when the excretory function was maintained artificially by dialysis and hypertension still supervened as long as the animal lived. Muirhead[3] showed that a kidney homograft restored the renal prival hypertension in the dog to normal level. On the basis of these observations, it was assumed that the hypertension which follows bilateral renal artery constrictions and complete nephrectomy is caused by a single mechanism, namely inhibition of the vasodepressor activity of the normal kidney.

The Renal Hypothesis

In 1898 Tigerstedt and Bergman[4] demonstrated that the renal tissue extract had pressor activity. They called this vasoactive substance renin. Prinzmetal[5] showed that a greater amount of renin was present in the kidneys of dogs with Goldblatt-induced hypertension. This was further substantiated by producing hypertension by transplanting ischemic kidneys into the neck of the normotensive animal, and demonstrating vasoconstricting activity in the renal venous blood from the ischemic kidneys.

Hypertensin

With the discovery of hypertensin, which differed from renin both biochemically and pharmacologically, the concept of "renin-angiotensin" was introduced; the enzyme renin is formed and secreted by the kidney and acts upon the renin substrate, which is an α_2 globulin component of the plasma. The resulting product, angiotensin I, is a decapeptid which is physiologically inactive. A second enzyme is needed in order to convert the inactive angiotensin I into the octapeptid angiotensin II, which is the active vasopressor substance.

Renin

Various experimental data summarized by Tobian[6] seem to indicate that the site of renin formation is the juxtaglomerular apparatus, and suggest that the specific granules of these cells are the renin. The structure of angiotensin is now known; it was recently synthesized by Bumpus and Page,[7] and by Rittel and his associates.[8] It is an extremely potent vasoconstrictive agent. The renin angiotensin pressor system represents the humoral mediator of hypertension caused by the ischemic kidney with the juxtaglomerular cells acting as regulators of renin secretions, by virtue of their sensitivity as "stretch receptors," to changes in arterial flow or pressure. A view differing from the preceding hypothesis is that renin is capable of inhibiting the antihypertensive function of the normal kidney. Therefore it is apparent that the exact mechanism associating the diseased kidneys with hypertension is not clear and none of the current hypotheses is capable of encompassing all the relevant experimental data.

The Clinical Aspects of Renal Hypertension

The clinical counterpart of the above experiments started with the idea presented by Ask-Upmark[9] in 1929 that unilateral renal disease might be related to hypertension. The first report of a successful nephrectomy planned to improve hypertension was published in 1937 by Butler.[10] A considerable number of nephrectomies have subsequently been performed with the hope of curing hypertension. However, since they were not based on solid criteria, the results were generally unsatisfactory. The cure rate at best in published series failed to exceed 26%.[11]

Specific Etiologic Factors

Unfortunately, the majority of patients with hypertension defy specific etiologic diagnosis; they are cured, however, when a specific cause is recognized and treated. Among such causes of hypertensive disease wherein the basic etiology can be determined and surgical therapy effectively employed are: pheochromocytoma, aldosterone adenoma of the adrenal glands, coarctation of the aorta, extra renal vascular lesions, and unilateral renal parenchymal disease amenable to nephrectomy.

Renovascular Lesions

Our present purpose is to consider the subject of renovascular hypertension. The vascular lesions capable of diminishing the renal blood flow include renal artery stenosis, renal arteriovenous fistula, renal artery occlusion, and aneurysms of the renal artery. By far the commonest lesion is renal artery stenosis. Although several different causes of stenosis have been reported, the majority of cases encountered are due, in order of their frequency, to arteriosclerotic changes, fibromuscular hyperplasia, or congenital deformities.

Although the true incidence of hypertension due to renal artery stenosis is not known, the number of cases will increase with the knowledge and high index of suspicion by the individual physician. The diagnosis has been made in all age groups from infancy to the eighth decade of life. The physician's attention should in particular be directed to renovascular hypertension under the following circumstances: hypertension in children and young adults, hypertension of recent onset, hypertension that rapidly progresses to the malignant phase, malignant hypertension, elevated blood pressure in patients with a history suggestive of renal vascular trauma, hypertension in the patient with arteriosclerosis elsewhere in his vascular system, sudden progression of mild hypertension, and hypertension which does not respond to the drugs available.

Diagnosis

The physical examination will not often permit a definitive diagnosis. However, the renal regions should be carefully auscultated for the presence of a systolic bruit. The absence of such a bruit in no way, however, diminishes the possibility of a renal arterial abnormality. In the majority of patients with renal artery stenosis, routine laboratory investigations are usually negative, including the urinalysis and blood urea nitrogen. Chest X ray and electrocardiogram only serve to signify the physiologic importance of the hypertension by demonstrating left ventricular hypertrophy and enlargement. Azotemia may develop in the presence of severe bilateral arterial occlusive disease resulting in renal insufficiency.

Intravenous Pyelogram

The intravenous pyelogram with serial visualizations of the kidneys at

Continued

30 seconds and at 1, 2, 3, 5, and 15 minutes may demonstrate one or many of the following findings: decreased renal size, delayed nephrogram, hyperconcentration of contrast material in the affected kidney, and notching of the pelvis or ureter due to collateral arterial blood supply around the stenotic area.

Radioisotope Renogram

For further evaluation, the following specialized examinations may be carried out: the radioisotope renogram, studies of differential kidney function, and renal arteriography.

The simplest of these is the radioisotope renogram. Following the intravenous administration of radioisotope-tagged Hippuran, the gamma rays can be counted and charted in relation to time. The initial peak of appearance relates directly to renal blood flow and has particular diagnostic importance.

Individual Kidney Study

Howard[12] introduced differential functional studies of the kidneys for the detection of unilateral renal involvement producing hypertension. The same principle was later modified by Stamey. The kidney with significant renal artery stenosis excretes less sodium, and the total urine output of such a kidney is also diminished. This study involves individual catheterization of the ureters and separately collecting samples of urine for volume and electrolyte measurements. Therefore the most impressive data are obtained with unilateral disease where there is an opportunity to compare the two sides. The data provides information about the function of the kidney to be correlated with the deformities demonstrated by arteriography.

Arteriography

Arteriography has been accomplished with reasonable risk and with excellent results. Two methods have been employed; the translumbar aortogram and the retrograde method through the femoral artery. Both methods have their advantages and disadvantages. However, lumbar aortography should not be employed in children. Retrograde technique has the advantage of complete mobility as to the point of injection and patient positioning, but should not be performed in patients with arteriosclerotic changes in the iliac and femoral arteries.

A typical arteriographic finding may be nonfilling of the renal artery, arteriosclerotic narrowing of the artery, fibromuscular strictures or bands, poststenotic dilatation, collateral vessels, and wedging or notching of the renal cortex during the nephrographic phase due to infarction or ischemia.

Therapy

Medical management of such patients never results in permanent cure. In fact, these patients are less responsive to drug therapy than patients with essential hypertension. The surgical management consists of either removing the kidney or repairing the artery. The most desirable procedure, however, is restoration of normal arterial flow for the following reasons: in bilateral disease this is the only method available, renal tissue is preserved, and the kidney supplied by the involved artery may be the better kidney in terms of its parenchyma.

Regarding the last statement, histologic studies from the two kidneys in instances of unilateral diseases have shown significant arteriolar nephrosclerosis on the side without vascular constriction. Because of this, delayed or even incomplete reduction of the blood pressure following an operation may be seen.

Nephrectomy

Removal of the kidney is recommended in the patient with unilateral disease who is a grave surgical risk, and in the management of an anatomically inoperable arterial lesion. Fortunately, these two circumstances are infrequently encountered.

Repair of the Renal Artery

In reconstructing the diseased renal artery, a variety of techniques have been employed. These include endarterectomy with or without the use of a patch; excision of the stenosed segment and reanastomosis; reimplantation of the divided end of the renal artery to the aorta distal to its origin; and finally, a bypass graft from the aorta to the renal artery. The splenic artery has been used to bypass the left renal artery stenosis. The operation is usually performed under hypothermia. A long midline or paramedian incision provides the best exposure, particularly when both arteries are involved. After the exploration of the involved segment, as well as the artery distal to it, pressure measurements are made by direct puncture of the artery proximal and distal to the stenosis. Bilateral renal biopsies should be obtained prior to the reconstruction of the diseased arteries, as they may be of value in the further management of the patient.

Results

The results of the surgical treatment in terms of control of the hypertension in properly selected cases have been gratifying. Sixty to eighty per cent restoration of normal blood pressure has been reported. The return of blood pressure to normal may take place as early as a few hours postoperatively, and as late as several weeks after the operation.

Renal Arteriovenous Fistula

Since the first report of renal arteriovenous fistula producing hypertension in 1928,[12a] approximately thirty more instances have appeared in the literature. The majority of these have had a congenital etiology, with trauma being the most common cause in the acquired group. The presence of a continuous thrill or bruit in the renal area has been common. Aortography usually shows a widely dilated and tortuous renal artery; in addition, prompt visualization of the renal vein and the inferior vena cava confirms the diagnosis. Venous oxygen saturation of blood obtained with a catheter introduced into the inferior vena cava at the level of the renal vein provides further diagnostic information. Relief of the hypertension can be achieved by nephrectomy. Associated renal parenchymal involvement by the fistula precludes direct arterial repair.

Continued

Renal Artery Aneurysm

As of 1959, approximately 150 instances of renal artery aneurysms were reported in the literature.[13] Their over-all incidence is considered to be 1% of all aneurysms. The etiology may be trauma, arteriosclerosis, infection or congenital deficiency in the arterial wall. Most are saccular and occur in the distal portion of the main renal artery or just beyond its primary bifurcation. In all cases reported the incidence of hypertension has been 15-20%. The cause and effect relationship is not clear. Microscopic or gross hematuria has been found in one third of the patients.[14] In addition to hypertension, other complications include renal infarction, rupture, or formation of an arteriovenous fistula. The diagnosis is made by aortography and treatment should usually be surgical, aiming at excision of the aneurysm and at arterial reconstruction, if possible.

Renal Artery Thrombosis

Acute thrombosis of the renal artery may result either from thrombosis of the previously diseased artery or from embolism. Total infarction or ischemia may give rise to severe hypertension which can be fatal. Typically, such acute ischemia is characterized by flank pain, hypertension, and in about 50% of the cases, occult or frank hematuria. Aortography provides the definitive diagnosis. Therapy consists of nephrectomy or direct arterial repair for main renal artery thrombosis, and subtotal resection of the kidney in instances of occlusion of the smaller branches of the renal artery.

Summary

Hypertensive patients fall into two general categories: those where a specific etiology amenable to surgical management can be defined, and a second group where the cause remains unknown. Despite progress in the medical management of the latter group, therapy is not curative. Hypertensive patients are cured, however, when a specific cause can be discovered and eradicated by an operation. Among the commonest of the surgically remediable hypertensive states are renal artery stenosis, renal arteriovenous fistula, renal arterial aneurysm, and renal arterial thrombosis. Patients who are especially suspected of having renovascular hypertension are considered. The manner and rationale of the workup and treatment are reviewed, with emphasis on the role of angiography and surgery. The results of surgical management with proper case selection have been gratifying.

Mixtures of the Magical and the Practical

Sometimes the witch doctor or the mental healer has used manipulations and even drugs, and the old herb doctor has taken care to gather his plants with a certain ritual or while mumbling spells, and only during certain phases of the moon. Furthermore, the herb doctor has often fallen from grace, scientifically speaking, and has prescribed a drug not because experience showed him that it was useful but perhaps because the astrologers believed that it and the disease to be treated were both under the protection of the same sign of the zodiac. Or perhaps because a walnut looks like a brain with all its convolutions, the old doctor gave powdered walnuts for insanity; or he gave red medicines for anemia and yellow ones for jaundice. Or he shaved elder bark downward to get a cure for vomiting and upward to get a cure for diarrhea!

And so it goes today; the faith healer calls in an obstetrician to help with a difficult case of labor, the spinopath prescribes diet and insulin for a diabetic, and the regular physician cures many a hysterical patient with a combination of pills, impressive apparatus, suggestion, and personal magnetism. Abstracts, Briefs and Commentaries

GASTROINTESTINAL COMPLICATIONS OF COLLAGEN DISEASES

Apparently intestinal infarction, perforation, and hemorrhage are being observed with increasing frequency in patients with vasculitis, lupus, and dermatomyositis. The difficulties of the surgical management under these circumstances are readily apparent. In view of these problems a study was made of 342 well documented cases of collagen disease from the Henry Ford Hospital.

The over-all instance of gastrointestinal complication was 5.8%, with a 21.1% incidence in polyangiitis, 9.6% in dermatomyositis, and 1.7% in systemic lupus.

Reviewing the types of complications leads the authors to suspect that a common pathogenesis applies to all of them. They believe there is a progressive destruction in small vessels leading to varying degrees of vascular necrosis, which is then followed by infarction, ulceration, hemorrhage, perforation, or varying combinations of these.

The implications of steroid therapy are discussed. Fourteen of the twenty patients developing complications were on steroids at the time. Obviously steroids do not prevent these catastrophes and may actually induce some of them. In some instances they may mask or disguise the severity of the problem.

Management of such complications in patients with collagen disease is a real challenge. In addition to judicious use of all the ancillary measures, surgery should be as prompt, conservative, and rapid as is consistent with an effective procedure.

Fifteen of this series of twenty patients recovered from their complication, but six of the survivors subsequently expired as a result of their systemic illness.

COMMENT: Perhaps the observation of increasing frequency of surgical complications in patients with collagen disorders attests to the increasing efficacy of medical treatment in salvaging these individuals for longer periods of more comfortable living. If this be so, we can anticipate a continuation of these difficult problems until the time when these vascular destructive processes can be reversed or prevented. Such studies as the one presented by the Henry Ford group are most instructive to the average clinician who encounters the problem much more infrequently.

INCIDENCE OF GALLSTONES

This investigation was carried out to determine the number of patients who developed gallstone disease after gastric resection for ulcer. The only report found in the literature by the investigators, bearing on this subject, was by Bernt, who in 1960 reported 12 cases of gallstone disease in patients who had undergone Bilroth II resection.

The follow-up showed that gallstone disease developed in almost every second patient within nine years after the Bilroth I resection. One hundred forty-eight patients were followed up with cholecystography between one and fifteen years after gastric resection. Only seven of one group of twenty-six had clinical symptoms of gallstone disease.

Gallstone disease was diagnosed in 42 per cent of the patients treated with Bilroth I resection, while the incidence was only 13 to 20 per cent in the Bilroth II group. They conclude that the Bilroth I operation may accelerate the development of gallstones as compared with the Bilroth II operation. Among the cases in which the mean period of 11 years had elapsed since treatment, 24 to 29 per cent of the patients who had undergone Bilroth II resection had gallstone disease.

This is an unusual report and should be of great interest to abdominal surgeons. I personally recall seeing no such report previously. It might be worthwhile to review the postgastric resection records in this country.

INSULIN, TOLBUTAMIDE, SEROTONIN, AND THE DUMPING REACTION

In a follow-up of previous observations on the beneficial effect of insulin on the dumping reaction, the authors have studied 33 postgastrectomy patients who had postprandial dumping. The characteristic vasomotor and gastrointestinal symptoms were significantly decreased in 29 of the 33 patients. Most of them were treated with both Orinase and Periactin, the latter being a serotonin antagonist. The level of benefit was not maintained for a consistent or a long period of time in some of these patients; however, the drugs would appear to be a very worthwhile addition for trial in patients who have this distressing problem.

The Orinase was given in .25 to .5 grams five or ten minutes before meals, and the Periactin in 4 to 8 millograms 30 minutes before meals.

FASTING FOR OBESITY

Intermittent facts — 5 to 14 days — in the correction and control of intractable obesity afforded the opportunity for clinical evaluation while the patients lost 0.7 to 1.8 kg. per day. A subjective sense of well-being and lack of hunger was attributed to the hyperketonemia provoked by the fast. Pregnancy, uncontrolled labile diabetes, peptic ulcer, and recent hepatic and myocardial disease were considered contraindications to the total fast. During the fast, water, noncaloric beverages, weak tea, and coffee were allowed. Serum electrolytes, cholesterol, CO_2, fibrinolytic activity, and steroid excretion were normal, although the urinary loss of NaCl exceeded the normal initially. Previously undiagnosed hypertension, diabetes, prediabetes, and cholelithiasis were frequent findings. Fasting reduced all cases of mildly elevated blood pressure to normal. Diets of 1,500 to 2,300 calories daily, with 1- or 2-day fasts at 7- to 10-day intervals, served to reduce the weight further while permitting a more liberal diet on a day-to-day basis.

GASTRIC CARCINOMA

One hundred twenty gastric carcinomas which had been operated upon were studied by Nadler and Cabrera from the standpoint of their microscopic classification. A modified Dukes' classification, in which types A, B_1, and B_2 revealed no lymph node involvement, was found to have a better prognosis for survival than types C_1 and C_2 where lymph node involvement was evident.

Total gastrectomy did not offer appreciably any better chance of survival than the subtotal gastric resection, and it was expressed that the procedure which removed the tumor completely, and not the one which would presumably provide the greatest chance for cure, was the procedure of choice.

Twenty per cent of those in the classification for Dukes' A and B had a survival rate of 5 years, while only 4.8 per cent of those in the classification of C and D attained a 5-year survival.

It was suggested that gastric washing be instituted as a routine part of a physical examination in patients over 50 years of age, in order to increase the possibility of discovering cancer at an early and optimal stage of operability.

No comparative diagnostic studies were made in regard to the findings from gastric washings and those of X ray. In this objective study it would appear that any procedure which allows an earlier diagnosis in carcinoma of the stomach should be worthwhile as a routine procedure.

THE SHELTERED WORKSHOP: A FRONTIER FOR MEDICINE

The words "sheltered workshop" sound new and strange in the ears of many Minnesota physicians, yet the best, (and largest) example of such workshops are the Goodwill Industries of Duluth, Minneapolis and St. Paul. Founded in Minneapolis in 1919, Goodwill Industries in these three cities currently employs almost 450 persons for a combined annual payroll of slightly less than one million dollars. The physician's role in the sheltered workshop program demands at the very least an awareness of both definition and scope of this program.

Continued

Including Goodwill, there are now twenty-one sheltered workshops in Minnesota, training 200-300 persons at a cost of $400,000 a year. The blind, deaf, mentally retarded and mentally ill are some of those to whom such training is directed. In addition, the victims of age, epilepsy, cerebral palsy, cardiac disease, and the partially paralysed are eligible for instruction. Training for regular employment is the goal of the sheltered workshop, but the handicapped individual often needs a sheltered work situation at the beginning of his re-educational period, allowing him to adjust both physically and emotionally to his handicap.

The purpose, then, of the sheltered workshop is to provide employment opportunities for the disabled individual unable to obtain work in regular or competitive job situations. Extending the idea of the sheltered workshop to community service is a far-reaching concept. In this instance, where there exists a local demand for temporary or part-time employment, the handicapped person is retained by the workshop as an employee. The employer then pays the sheltered workshop for the service rendered. The workshop provides supervision, prevents exploitation and assumes reponsibility for insurance, tax records, etc. Experience with this plan has been very encouraging.

Not all "trainees" become employable, but experience indicates that about half of those trained are ultimately able to obtain regular jobs. With 3000 to 4000 severely handicapped persons in this state at the present time, the potential value of the program is obvious.

One of the acute problems facing the expansion of the sheltered workshop program concerns the use of the subminimum wage. Legal precedent has been established, allowing the workshop or employer to pay the handicapped individual according to what he can earn in terms of productivity. Thus minimum wage laws may be waived and this has incurred opposition from union organizations and others. However, the subminimum wage is allowed only for the severely disabled, certified as unable to earn a minimum wage. Misunderstood, this provision of the law is looked upon as a social and economic regression. But for the disabled individual, the choice is not that between a minimum and subminimum wage — it is between a subminimum wage and nothing, nothing but illness and frustration. Psychologically, a subminimum wage is at least a foot in the door of self-reliance and independence.

Thus the concept of adding life to years receives added impetus from the sheltered workshop, providing job training, counseling and supervision to those severely disabled persons in our communities. Because this is a health-related facility dealing with the life and happiness of our patients, as physicians we owe it to ourselves to keep abreast of these times.

John V. Thomas, M.D.
Duluth, Minnesota

MANAGEMENT OF ESOPHAGEAL BURN

When esophageal injury from corrosives is established, items of central importance to management are steroid therapy and antibiotics. Prior to starting such therapy, however, a thorough esophagoscopic examination is of the utmost importance. This is particularly true if the program of management includes dilations, and these latter should be reserved for cases in which a tendency to stricture is definitely demonstrated. The authors report on a series of 100 consecutive patients. Of these, 47 were known to have normal esophagi at their last examination. Only 3 patients developed strictures. Except for the initial necessity of tracheotomies on 2 patients on admission, the only complications noted were the occasional development of moon-face. This symptom disappeared one to three months after the steroid was stopped. There were no known significant complications.

Of the 100 patients, 70 were children three years old or younger. The other 30 were over ten years old, and 25 were attempted suicides. The distribution between white and Negro patients was about equal, but there was a high proportion of persons of Latin American extraction in the white group. Solid lye was the noxious agent in 54 per cent, but the administration of water, milk, vinegar, etc., probably liquefied it to some extent in many cases. Most of the burn cases were due to solid or liquid lye, but sulphuric and hydrochloric acid, lysol, and inorganic phosphorus were other causes.

Here is the program outlined for management of lye burns: Steroid and antibiotic therapy are started as soon as an esophageal burn, or a reasonable likelihood of it, is established. (a) Suggested prednisone schedule: First four days, 60 mg. (20 mg. every eight hours) ; next four days, 55 mg. daily (20-15-20) ; next three days, 40 mg. daily (15-15-10) ; next three days, 30 mg. daily (10 mg. every eight hours) ; next three days, 20 mg. daily (5-10-5) ; next two days, 10 mg. daily (5-0-5) ; last two days, 5 mg. daily. (b) Tetracycline while on prednisone therapy. (c) Potassium supplement given orally. (d) Nasogastric tube or string (optional). (e) Esophagoscopy in one week and one month. (f) Chest X ray weekly. (g) Barium swallow at one month. It is believed that the relatively high prednisone dosage during the early stage of the injury suppresses granulation tissue and fibroblastic activity. Children and adults get the same prednisone dosage except in adults who are found to have severe esophageal burns at the initial esophagoscopic examination. Such adults are maintained on 60 mg. prednisone for an additional period of two weeks. Small nasogastric tubes are passed in patients showing evidence of severe oropharyngeal burns or where oral intake of food and fluids is not sufficient. The tube is left in place until soft foods can be swallowed easily. The initial esophagoscopic examination is made within two to five days under general anesthesia both for children and adults. The entire esophagus is examined in order to determine fully the extent of the injury. If at the end of the month of therapy the esophagus is completely normal, the patient is discharged completely, but if any deviation from normal, even mild hyperemia, is found, the patient is seen again two to six months later. If there are severe burns, particularly with granulation tissue, repeat esophagoscopy is done ten days later, with dilations by Hurst bougies if there appears to be narrowing of the lumen.

ANGIOGRAPHY IN CURRENT PRACTICE

In this short article the authors discuss the advantages, limitations of angiography, the criteria for patient selection, the principal problems involved with contrast media, catheter methods and noncatheter methods.

Pointed out is the fact that there is no area of the human body that cannot have the blood vessels visualized to demonstrate arteriosclerotic conditions, inflammatory conditions, or neoplastic conditions. In many cases angiography and correlation with laboratory studies can make an exact diagnosis impossible by physical examination methods. In the future the need for study of the vascular system in grafts and organ transplantation is evident. Pointed out is the fact that angiography is a procedure that requires great skill; complications can be minimized by discouraging occasional angiographers. This is especially true in that the arteriographer must know a great number of different techniques which can be selectively fitted to the particular patient. The authors feel that the catheter methods are needed in selected cases but that the noncatheter methods of angiography are more advantageous and cause less difficulty. In conclusion they feel that angiography of any form will be recognized as a routine radiologic procedure that requires co-operation between the radiologist and vascular surgeon.

This excellent short article succinctly gives the clinical indication for angiography. It also points out that the real danger in the technique is not the technique per se but the individual who performs the study. I wholeheartedly agree that angiography is a very specialized field which requires an intense interest and experience. There are numerous institutions and individuals willing to teach the techniques to those physicians willing to learn.

The procedures require a team effort on the part of the radiologist and the vascular surgeon, as complications that occur usually require the services of a vascular surgeon. Therefore, it is my opinion that all procedures should be done as a team.

Book Reviews

First we shall want the pupil to understand, speak, read, and write his mother tongue well. — H. G. Wells

THE CARE OF THE GERIATRIC PATIENT — E. V. Cowdry, Editor, 2nd ed., Saint Louis, C. V. Mosby, 1963. 566 pages, index, references.

Writing both as a gerontologist and a geriatric patient, Dr. Cowdry attempts to fill the gap between abstract studies of the aging process and the care of the aged. As editor, he has compiled a comprehensive manual of geriatric medicine, psychology and sociology by a distinguished group of contributors including Paul Dudley White, Warren Cole and Paul Starr.

The comfort and well-being of the physiologically deteriorating person is the theme. Problems are investigated from the standpoint of the patient and his physician, and of the aging population and its place in the community. Equal space is given to the medical and surgical problems of preventive medicine and specific therapy, to the psychology of the aged and their psychiatric reactions, and to the really major and often neglected problem of the life of the individual in the community. Home-care programs, nursing homes and rehabilitation receive their rightful places.

Designed primarily for physicians, the nontechnical style and comprehensive scope make this manual a valuable tool for paramedical personnel and for social and government agencies concerned with geriatrics.

Extensive bibliographies following each chapter are a ready source for further reading in particular areas of interest.

In the forward, Dr. I. S. Ravdin states that the perplexities of geriatrics are here to stay unless some catastrophic event leads to mass death of those suffering from geriatric disorders; or, through some method not now available to us, "old age" can be prevented or delayed. The authors are to be congratulated for bringing together available knowledge about the aged.

THE PROCESS OF EVOLUTION — Paul R. Ehrlick, and Richard W. Holm, McGraw Book Company. Inc., 1963. 347 pages.

This publication follows a well-ordered plan wherein any given chapter is built upon foundations laid down in the preceding chapter. The authors have used the principles of evolution to develop their views on the pattern of interaction of matter.

Beginning with the basic elements found in organic compounds, they build amino acids, nucleic acids, proteins, genes, cells and organisms. After giving a short background of genetic mechanisms, they show how these work to alter populations as their environment changes.

While having no practical clinical application, this book provides a great deal of stimulus to consider individual variation, and the place or purpose of disease processes on populations.

Hennepin County General Hospital
Minneapolis, Minn.

THE CIGARETTE HABIT — AN EASY CURE — Arthur C. Cain, M.D., Doubleday & Co., New York

For the habitual cigarette smoker who needs an additional crutch to stop the bad habit, this small pocket-sized paperback provides the interesting details for a "Q-Day," Q for quit, no doubt. It allows the habitue a 21-day guilt-laden period in which he may, like a slave, smoke his loved tobacco but not his usual brand.

The last chapter provides some interesting medical and vital statistics.

This book is written for the smoker, but it can be well recommended by the physician to his patients who have become a slave to their pack.

Minnesota State Board of Medical Examiners

Are Basic Science Laws Effective?*

I must first briefly review for you our philosophy in Minnesota by telling you of the background of the Basic Science laws passed there in 1927. That was 38 years ago, and there has never been a serious suggestion from any responsible person in the State that they be repealed. Wisconsin has passed the 40 year mark in its Basic Science Laws and still supports them vigorously.

In general, there is no question but what the practice of medicine is on a different plane from that of the other so-called healing arts. It would only take up time to go into this truth at any length. The void between our scientific medical practice and the cultist practice is so deep that only the ignorant and those intentionally misled can fail to see it. Our medical men in Minnesota recognized this fact of life many years ago. They considered a means by which they could maintain our high standards and minimize the inroads of the cultists who were thriving and seemed to be about to flourish to even greater heights. It is pertinent here to quote from an early history of medicine in Minnesota. Back in the territorial days of 1853, when our State Association was founded, "the settlements and the trails, the river fronts and the trading posts of the new Minnesota Territory already abounded in quacks and Indian healers of all descriptions." By contrast, may I call your attention to a few facts about Minnesota today.

The Mayo Clinic, for instance, has just concluded its Centennial Year; the doors of the University of Minnesota Medical School were opened 75 years ago and that event is being celebrated this year; the Mayo Foundation for Medical Education is now 50 years of age — that Foundation being a unique alliance between a great public medical school and a world famous private clinical and teaching facility.

Medical men in Minnesota, recognizing the high level of medical practice, in contrast to the low level of the cults, hit upon the Basic Science concept and in 1927, succeeded in convincing our legislators that a Basic Science Law would help to maintain medical standards and, at the same time, freeze out many of the irregulars engaged in the healing arts. The legislators realized, after it was pointed out to them by the physicians, that Basic Science legislation would actually force the cultists to pay for their own eradication.

Before telling you of the results accomplished by the 1927 action of our legislature, I shall briefly explain our attitude toward the arguments that are commonly heard against Basic Science laws.

In the first place, we do not believe that the creation of a Basic Science Board constitutes any impediment to the operation of medical practice laws. What could the impediment be? All we are doing, actually, is to take six subjects out of the medical examination and put them in a separate examination. Each person who professes to be engaged in healing in the state must pass that examination before he can apply to his particular board for a license to practice in his field. The medical man is required to pass these subjects as part of his regular examination. In the absence of a Basic Science Board, the cultists would determine their own tests of basic knowledge and education. It is painful

Continued

---

*Presented at the meeting of the Federation of State Boards, February 8, 1965.

to contemplate the sham type of examination that would be given in Basic Science by a cultist board. I am sure their examinations would be as much a fake as are their theories of practice.

Opponents of the Basic Science laws seem to feel that the greatest objection to such laws stems from the fact that a man going to a Basic Science state must acquire a Basic Science certificate. In other words, the objectors feel that Basic Science laws are an obstacle to universal reciprocity. I shall outline my attitude toward this objection in a few brief statements:

1. In my years on the Board, I have never seen a qualified physician, genuinely interested in practicing in our State, who was prevented from acquiring medical licensure because of the Basic Science law. A few delays have been observed, yes — but never a stymie.

2. Our Basic Science laws permit reciprocity between accredited agencies. Surely there can be no objection for Basic Science Boards to recognize this and to grant reciprocity in Basic Sciences on the basis of legitimate medical examinations given by the non-Basic Science State Boards of Medical Examiners. Our Basic Science Board does this in many instances and I think our State Boards should encourage the practice. We have nothing to fear in this regard. The Basic Science laws are as strong as the State Boards that enforce them. There will be no recognition of examinations by unqualified Boards such as those of chiropractors or other cultists in our lifetimes, or the foreseeable future.

3. There are 50 states and half of them have seen fit to enact Basic Science laws. It seems that it would be as reasonable to pass such laws in all the states as to abolish them in all. This would be another way of acquiring uniformity and universal reciprocity, if that is truly desirable.

4. In my mind, universal reciprocity is still a moot question. Does medical licensure in one state indeed give a vested right to practice in another? Surely each state has the right to make its own laws. I have the feeling that general reciprocity would bring about a decided change in the pattern of tenure of physicians in particular locations. In many instances this might not be beneficial or advantageous to the individual, or to the public. Those who experience the need to escape — the need to make a fresh start in another state — frequently do not improve things by moving. Yet I feel that these are just the persons who may change locations and go to a distant state more or less on a whim, or in the hope of magic relief from their difficulties. Strictly enforced, Basic Science laws are more apt to keep such individuals from moving than they are to discourage more desirable practitioners who have legitimate reasons for moving. But, this is unproven ground and it may represent straying from our topic.

Now I shall show a slide summarizing our experiences:

Minnesota Annual Registration

	1928	1963	Increase
Physicians	3442	8681	5239
Chiropractors	493	539	46

I leave it up to this audience to decide on the effectiveness of Basic Science laws in our State.

J. P. Medelman, M.D.

Medical Economics

FOR OUR ELDERLY:

WILL IT BE MEDICARE
OR
WILL IT BE ELDERCARE?

A new eldercare program, superior in all respects to the King-Anderson, the so-called Medicare plan, has been introduced in Congress.

Representatives A. Sidney Herlong, Jr., (D., Fla.) and Thomas B. Curtis, (R., Mo.) are the authors of the proposed legislation which would cover payment of physicians' care, surgical and drug costs as well as hospital and nursing home care.

The introduction of the Herlong-Curtis Eldercare Bill (H.R. 3727) represents a breakthrough of historic importance to all citizens in the drive to provide people over 65 with a wide range of health care to meet their individual needs.

This bill is the best piece of legislation dealing with the health care needs of the elderly now before Congress. Careful analysis of H.R. 3727 indicates that it will assure more benefits at less cost to the taxpayer, than any other measure for people 65 and over who need care and can't afford to pay for it. It provides for sound financing and experienced administration. The tested machinery of the established insurance systems, including Blue Cross and Blue Shield and health insurance companies would be used.

Doctors Support New Eldercare Proposal

The medical profession recently recommended and now supports wholeheartedly the principles embodied in the Herlong-Curtis eldercare proposal.

Details of the Doctors' Eldercare Program were announced to the public on January 9, 1965, by Doctor Donovan F. Ward, President of the American Medical Association. Eligibility for benefits under the Herlong-Curtis, physician-backed eldercare proposal would be determined quickly before illness strikes — and without a welfare department type of investigation.

Persons over 65 would qualify for a medical care policy submitting a simple statement of income.

Medicare Means More Taxes

The Herlong-Curtis Eldercare Proposal would be financed by federal-state matching funds through an extension of a Kerr-Mills program that already exists.

The Medicare tax plan would call, by con-

Continued

trast, for higher payroll taxes on all wage earners to pay benefits for everyone over 65 — the rich as well as the needy. The tax burden would fall heaviest on those least able to pay. For example, the $5,600-a-year worker would be forced to pay as high a tax as the $56,000 executive. Here is a detailed question-and-answer explanation of the various issues involving medical care for older people.

Q. What is the Kerr-Mills Law and how does it work?

A. The Kerr-Mills law was passed by Congress in 1960. The law enables the individual states to guarantee to every aged American who needs help the health care he requires. In addition to the more than 2,000,000 covered by Old Age Assistance, the law is designed to benefit all other older persons who are ordinarily self-supporting but unable to meet the cost of a serious or prolonged illness. It helps those who need help. Each state can pattern the program to meet its own particular needs. It is administered locally where the individual needs of the aged are known. By helping *only* those who need help, it avoids waste of tax dollars. It is financed by federal-state matching funds and is being implemented as rapidly as most federal-state programs.

Kerr-Mills In Minnesota Has Splendid Record

Q. Does Minnesota have a Kerr-Mills Law?

A. Yes. Implementing legislation was passed by the 1963 legislature. The program became effective July 1, 1964.

Q. Who is eligible for Kerr-Mills benefits in Minnesota?

A. Applicants must be 65 or over and must have an established abode in a given county of Minnesota. If temporarily absent from the state the applicant must still be deemed a resident.

Q. Must applicants be paupers to receive Kerr-Mills benefits?

A. Definitely not. In Minnesota a married couple is allowed an annual income of $2400. An applicant for MAA and his spouse may have equity in real property up to $15,000 plus liquid assets of $1,000. For an individual the annual income limit is $1800, the real property limit is $15,000 and liquid assets can be no greater than $750.00. These do not include personal and household effects, or a prepaid burial plot, or the cash surrender value of each person's life insurance up to $1,000.00.

Q. What is the financial responsibility of Minnesota Kerr-Mills applicants?

A. The individual applicant, or he and his wife together, must have spent or obligated himself or themselves to spend $200.00 on health care during the preceding 12 months. (Health Insurance premiums can be included in this "deductible" amount). *All* benefits from any private health insurance must be applied first to the cost of any recipient's care before he is eligible for Kerr-Mills benefits.

Kerr-Mills Offers Generous Benefits

Q. What type of benefits does the Minnesota Kerr-Mills program provide?

A. The Minnesota Kerr-Mills implementation provides *total health care,* in the hospital, nursing home, doctors' office, patient's home, clinic, or diagnostic center. It covers surgery, drugs, dentist care, appliances, ambulance service, home nursing, rehabilitation, necessary laboratory services, preventive care, and immunizations. There is no time limit to the benefits. They continue for the duration of the illness.

Q. How is the Minnesota Kerr-Mills program administered?

A. The regulations are promulgated by HEW and Minnesota Department of Public Welfare. Actual case work is performed by local County Welfare Board.

Q. How is the Minnesota Kerr-Mills program financed?

A. The federal government provides 56.4% of the health care dollars expended and 50% of the actual administrative cost of the program. The remaining 43.6% is divided 50-50 between the state and county.

Q. Must Minnesota Kerr-Mills applicants sign a lien?

A. No. The federal Kerr-Mills act does not permit liens.

Q. How many Minnesotans have received help under the Kerr-Mills Law?

A. After five months of operation, approximately 12,500 persons have received benefits. In November, 1964, an average payment of $206.02 had been made for each of the 11,754 recipients. The Department of Public Welfare originally estimated the monthly cost at $225.00 per patient.

Q. Will more people be assisted under the plan?

A. Yes, the Department of Public Welfare feels that the caseload will stabilize at about 18,000 recipients for the ensuing year. Approximately 140,800 people could be covered by the benefits.

Q. How much does the Minnesota plan cost?

A. For the 1964-65 fiscal year, the state legislature appropriated $7,650,000. A like amount was to be matched by the 87 counties. The federal reimbursement at the present time is 56.42 per cent of the total cost. A spokesman for the Department of Public Welfare has stated that "our utilization and expenditures have not been as great as we expected." Currently expenditures are 12-15% under original estimates.

Medicare Offers Many Questions — Few Answers

Q. What is *Medicare* (in contrast to Eldercare)?

A. Medicare is a system of compulsory hospital insurance for elderly persons financed through the Social Security system. The King-Anderson Bill, a proposal now before Congress, is an example of the compulsory approach to Eldercare.

Q. Who would be eligible for Medicare benefits?

A. All persons over 65 who are currently receiving Social Security cash benefits or benefits under the Railroad Retirement Act. All persons who could receive Social Security cash benefits except that they are continuing to work and are earning self-support incomes. All who, before 1968, have attained or will attain the age of 65 and who are not covered by Social Security or Railroad Retirement Benefits. All who, after 1968, will have worked for at least three quarters on a Social Security covered job for each calendar year elapsing after 1965 and before the year in which they attained age 65.

King-Anderson Benefits Are Limited

Q. What benefits would the present version of the King-Anderson Bill provide?

A. 1. Limited Hospital Care — Up to a 60 day stay in a semi-private room in a hospital during a benefit period, after the current per diem rate for one day is paid. The per diem rate is about $40.00-$44.00.

2. Limited Post-Hospital Services — Up to 60 days per benefit period in a hospital-affiliated post-hospital facility. This can be a nursing home, but the patient must be transferred from a hospital before he can qualify and the nursing home must provide 24-hour nursing service, supervised by a registered professional nurse, and it must have and use a utilization review plan.

3. Home Health Services, including 120 visits in 1966; 240 visits in any calendar year after 1966. Visits may include nursing care under supervision of a registered nurse, physical, occupational, or speech therapy, etc. Home health care can be furnished only by persons working for tax-exempt public or private non-profit organizations.

4. Outpatient Hospital Diagnostic Services including 30 consecutive days after paying one-half of the current per diem rate for one day. The per diem rate is about $40.00-$44.00.

Q. What benefits would be excluded from the King-Anderson Bill?

A. Surgery; doctor's care, at home, at the office, or in the hospital; medicine, drugs, etc., furnished outside of approved hospitals or convalescent homes; dental care; outpatient therapy, eye glasses, wheelchairs, crutches, and other health appliances.

Medicare Tax Would Whittle Pay Checks

Q. How would taxpayers pay for Medicare?

A. The federal government will create a new payroll deduction tax called the Federal Hospital Insurance Trust Fund. In addition to paying Social Security taxes, federal withholding taxes and state withholding

Continued

taxes out of one's paycheck, all workers covered by Social Security will pay a new "Medicare" tax. Together, employees and employers will pay .6 of 1% of the first $5600 earned income for the new tax. This will increase until 1969 when the tax rate will be .9 of 1% of the first $5600 income. The self-employed will begin by paying .45 of 1% of $5600 and by 1969 the rate will be .675 of 1%.

Q. How much would the Social Security tax be increased to pay for Medicare?

A. The new rate will be based on $5600 a year income. In 1966, the tax paid by employees and employers each would be increased from the present $174 per year to $238. The tax on a self-employed individual would be increased from $258.20 to $358.40. In 1971 and thereafter, the tax on the employee and employer each would be increased from the presently scheduled $222 per year to $291.20. The presently scheduled tax of $331.20 on a self-employed individual would be increased to $436.80.

	Self-Employed		Employer-Employee (each)	
	Present	Proposed	Present	Proposed
1966-1967	6.2%	6.4%	4.125%	4.25%
1968-1970	6.9%	7.5%	4.625%	5.0 %
1971 & thereafter	6.9%	7.8%	4.625%	5.2 %

Eldercare — Medicare Differences Are Great

Q. How would the doctors' new eldercare plan differ from Medicare?

A. The doctors' eldercare program would provide a wide range of medical care for over-65 Americans needing financial help in meeting illness costs, including payment for physicians' care, including surgical and drug costs, as well as hospital and nursing home charges. Compare these wide-ranging benefits with the "medicare" tax proposal which offers a restricted number of days in a hospital or nursing home, plus limited outpatient care, all of it amounting only to an estimated 25 per cent of the usual cost of an illness. Under the doctors' program, care would be related to individual needs.

Q. How would the protection offered by the doctors' eldercare program be financed?

A. The doctors' eldercare program would utilize Blue Cross and Blue Shield plans and health insurance companies, assuring experienced administration. Policies would be available to protect the elderly from illness costs. Purchase of the policies would be financed entirely, or in part, by state-federal matching funds, depending upon an individual's ability to pay. These companies and non-profit organizations are already set up. They have the experience gained in providing health insurance protection to millions of Americans. The program would utilize an established insurance system. It would not undermine the system, as medicare would, through unfair government competition.

Q. How would needy persons apply for aid under the doctors' plan?

A. By filing a simple statement of income with the appropriate state agency. Those with incomes below, or within, limits set by the states would automatically become eligible for benefits. Those reporting incomes lower than the state's lowest figure would receive paid up policies from the public funds. Those with incomes between the minimum and the higher limit set by the states would have part of their insurance charges defrayed from the matching fund pool, on a sliding scale. The higher the income, the less would be paid by government. Thus, the degree of need would be the measure of the amount of financial help received.

Q. How would the doctors' eldercare plan be administered?

A. The medical profession is hopeful that the program would be administered by state health departments, the logical arm of government to handle health problems. This would be authorized under the proposal. Thus, the knowledge and administrative experience of both health officials and insurance carriers could be utilized, without a welfare type investigation.

Q. Would a new federal program be necessary?

A. The machinery already exists in the Kerr-Mills act for providing federal help to the states on a matching basis to assure the aged the health care they need. Only a few simple amendments to Kerr-Mills and existing state laws would be necessary to put the doctors' plan in operation; that is, legislation (1) providing for a simple income declaration; (2) utilizing the private carriers in providing the help, and (3) permitting administration of the program to be placed under the state health departments.

Public Would Benefit From Herlong-Curtis Proposal

Q. How would this benefit the public?

A. By taking advantage of a program that is already in existence and operating, the doctors' plan would avoid the necessity for creation of a costly, new federal bureaucracy to administer a centralized program from Washington. By providing aid on a basis of need, the doctors' plan would assure that both federal and state dollars were being used to provide care where it is most needed. Available resources would be concentrated on bringing hospital and medical care to those unable to pay for it. Millions would not be squandered on new payrolls, or on financing care for the self-supporting and the well-to-do so that no one could receive more than partial care at best.

Q. What would be the function of the federal government under the doctors' plan?

A. The federal government would provide funds to help the states pay the premiums for those who need help. Historic relations between the states and the federal government would be preserved, with maximum authority and responsibility remaining with the states to guard the interests of their own citizens instead of delegating the responsibility to a central authority in Washington. With the experience of private insurance companies, and of the Blue Cross and Blue Shield plans at the service of the program, a more efficient use of public money would be possible.

MD's Plan Would Not Affect Freedom of Medicine

Q. How would the freedom of medicine be affected?

A. Under the doctors' plan, as under Kerr-Mills, the federal government would have no reason to intervene in the practice of medicine. The Secretary of Health, Education and Welfare, for example, would *not* be required to have "agreements" with hospitals, or be empowered to audit personal medical records in connection with paying the hospital or nursing home bills for beneficiaries of a federal program. An elderly patient would *not* be limited to seeking care in those institutions, only, which are eligible by law or under the Secretary's regulations to participate in a federal program. Protected by his insurance policy, he would retain his freedom of choice.

Q. Would the doctors' eldercare program require any increase in payroll taxes?

A. The Doctors' Eldercare Program would not require a burdensome payroll tax increase on the nation's workers and employers. It has been estimated that the "medicare" tax program, furnishing benefits to *everyone* over 65, the wealthy included, would soon cost $5 billion a year. While costs of the doctors' program have not been calculated, it is reasonable to assume they would be substantially less than the "Medicare" tax program, even with greater benefits. Costs of the doctors' program would be subject to factors unknown at this time — for example, the minimum and maximum levels of income to be established by the various states for eligibility. The doctors' program would be limited to those who need help and a portion of the elderly who would qualify would contribute part of the cost themselves. These factors would minimize costs.

Harold W. Brunn, Executive Secretary
Minnesota State Medical Association

Though one may conquer a thousand men a thousand times in battle, he who conquers himself has the more glorious victory. — Buddha

He is the best physician who knows how to distinguish the possible from the impossible. — Herophilus B.C. 300

the problem: diabetic . . . overweight . . . unresponsive to diet alone

the answer: "...if dietary control seems to be unsatisfactory . . . [and] if the patient is overweight . . . our first choice is phenformin [DBI] since this is the only oral hypoglycemic agent commercially available at present which does not promote fat deposit."[1]

"...with phenformin [DBI] there may be less preferential stimulation of fat synthesis in the obese, diet-resistant diabetic, favoring both blood sugar and body weight control."[2]

to manage the stable adult diabetic who is overweight and unresponsive to diet alone

DBI® DBI-TD

tablets 25 mg. **timed-disintegration capsules 50 mg.**

BRAND OF PHENFORMIN HCl

DBI together with a proper diet usually affords effective control in the overweight ketoacidosis-resistant diabetic . . . reduces high blood sugar and elevated serum insulin levels, and encourages gradual weight loss toward normal.[3] For the ketoacidosis-prone diabetic, however, insulin is still the essential hypoglycemic drug.

side effects: Gastrointestinal, occurring more often at higher dosage levels, abate promptly upon dosage reduction or temporary withdrawal. precautions: Occasionally an insulin-dependent patient will show "starvation" ketosis (acetonuria without hyperglycemia) which must be differentiated from "insulin-lack" ketosis which is accompanied by acidosis, and treated accordingly. Lactic acidosis has been reported in nondiabetics and diabetics treated with insulin, with diet, and with DBI. Question has arisen regarding possible contribution of DBI to lactic acidosis in patients with renal impairment and azotemia and also those with severe hypotension secondary to myocardial or bowel infarction. Periodic B.U.N. determinations should be made when DBI is administered in the presence of chronic renal disease. DBI should not be used when there is significant azotemia. Any cardiovascular lesion that could result in severe or sustained hypotension, which may itself lead to development of lactic acidosis, should be considered cause for immediate discontinuation of DBI at least until normal blood pressure has been restored and is maintained without vasopressors. Should lactic acidosis occur from any cause, vigorous attempts should be made to correct circulatory collapse, tissue hypoxia, and pH. **contraindications:** Severe hepatic disease, renal disease with uremia, cardiovascular collapse. Not recommended without insulin in acute complications of diabetes (metabolic acidosis, coma, severe infections, gangrene, surgery). pregnancy warning: *During pregnancy, until safety is proved, use of DBI, like other oral hypoglycemic drugs, is to be avoided.* Consult product brochure for full information.

History of Medicine

William Clowes (1540-1604)

That the times produce the man has been irrefutably demonstrated throughout history — but nowhere so patently as in medical history. When challenge arose, it was met!

One such notable challenge was the treatment of gunshot wounds which, in England's centuries of almost unremitting warfare, presented multifarious problems unfamiliar to surgeons prior to the discovery and use of gunpowder.

One of the men who met the challenge was William Clowes, a 16th-century English army surgeon, whose wide observation and practice with soldiers wounded in battle resulted in the work, "Proved Practice for Young Surgeons," used as a reference and text by students.

With what ingenuity and skill Clowes solved one troublesome problem is described in Parker's "Early History of Surgery in Great Britain:"

"In 1573 a soldier named Giles was shown him, who had been wounded three years previously in Flanders by a bullet entering the left iliac fossa. There was still a deep sinus there, which was seriously affecting his health, and the situation of the bullet could not be determined. Clowes made futile efforts to reach it by long probes. He then enlarged the orifice, introduced sponge tents, and even caustics, but he was still unable to get a flexible probe down to find the bullet. He bethought himself that a liquid might penetrate, and injected through a long tube a solution containing alum and sublimated silver, leaving it in while the patient was kept in a suitable position. Twenty-three hours after, pain and swelling began in the right buttock near the anus, which was poulticed. Next day he cut down on the swelling, found the bullet there, and removed it. After a series of dressings and injections the wounds healed up completely."*

Clowes, however, was not the only pioneer in the field of battle injuries; there were others. One might almost say that during her military history England produced a new breed of men — her military surgeons. Instigated by a drive to meet a new and compelling challenge, these men present convincing historical substantiation for the materialistic conception of history: the theory that the times produce the man.

Doesn't think of himself as the reckless type at all. But he goes on taking the *big* risk. Clings to a habit which causes 100 deaths every day from lung cancer and which contributes to many, many more from coronary artery and respiratory diseases. Studies show that the death rate from lung cancer alone for cigarette smokers (one-pack-a-day or more) is 10 times higher than for nonsmokers.

Nobody says it's easy to stop. But living *that* dangerously often winds up in not living at all.

in peptic ulcer therapy—"little things mean a lot"

it's the sum total of many subtle advantages that makes glycopyrrolate a superior anticholinergic

ROBINUL® FORTE glycopyrrolate 2 mg. per tablet

ROBINUL®-PH FORTE

glycopyrrolate 2 mg. / phenobarbital 16.2 mg. / (warning: may be habit forming)

The remarkable efficacy of Robinul (glycopyrrolate) in the treatment of peptic ulcer cannot be attributed to any single characteristic of the drug. Rather it is the sum total of several subtle pharmacologic advantages that enables this anticholinergic to make such a significant contribution to the total ulcer regimen.

Epstein[1] found glycopyrrolate's intensive antisecretory action to be exemplary. Breidenbach[2] was impressed by its pronounced antispasmodic effects. And Young and Sun[3] reported that a 2 mg. oral dose "did not affect gastric emptying or intestinal transit time. . . ." According to Slanger[4], the absence of annoying side effects is an important plus factor ". . . for it permits ready individualization of dosage for control of mild to severe symptoms." Posey[5] sums it up when he says, "In effect, with glycopyrrolate, one approaches an ideal agent for the management of peptic ulcer. With it a vagolytic effect may be obtained without interfering with gastric emptying—the medical equivalent to vagectomy plus an adequate drainage procedure."

We invite you to try Robinul (glycopyrrolate) in your practice. Discover firsthand how several subtle advantages add up to make it the superior anticholinergic agent.

BRIEF SUMMARY

INDICATIONS: In addition to its primary indications for duodenal and gastric ulcer, glycopyrrolate is indicated for other G-I conditions which may benefit from anticholinergic therapy. Robinul-PH Forte (glycopyrrolate 2 mg. with phenobarbital) is indicated when these situations are complicated by mild anxiety and tension.

CONTRAINDICATIONS: Glaucoma, urinary bladder neck obstruction, pyloric obstruction, stenosis with significant gastric retention, prostatic hypertrophy, duodenal obstruction, cardiospasm (megaesophagus), and achalasia of the esophagus, and in the case of Robinul-PH Forte, sensitivity to phenobarbital.

PRECAUTIONS: Administer with caution in the presence of incipient glaucoma.

SIDE EFFECTS: Dryness of the mouth, blurred vision, urinary difficulties, and constipation are rarely troublesome and may generally be controlled by reduction of dosage. Other side effects associated with the use of anticholinergic drugs include tachycardia, palpitation, dilatation of the pupil, increased ocular tension, weakness, nausea, vomiting, headache, dizziness, drowsiness, and rash.

DOSAGE: Should be adjusted according to individual patient response. Average and maximum recommended dose is 1 tablet three times a day: in the a.m., early p.m., and at bedtime. *See product literature for full prescribing information.*

Also available:
Robinul® (glycopyrrolate 1 mg. per tablet)
Robinul®-PH (glycopyrrolate 1 mg. per tablet)
phenobarbital 16.2 mg.

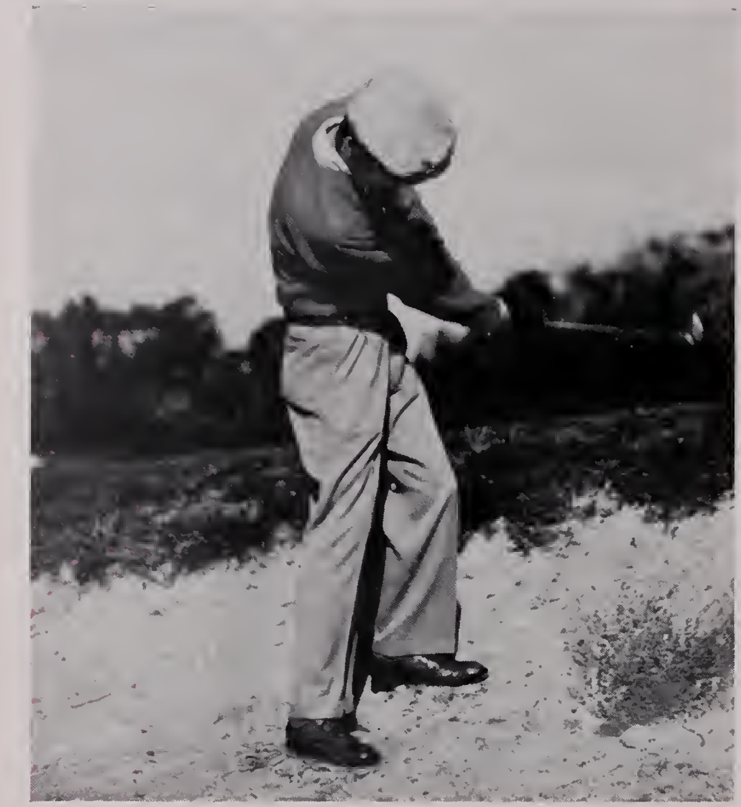
A. H. ROBINS COMPANY, INC., RICHMOND, VIRGINIA | PHARMACEUTICALS | RESEARCH **Robins**



Your patient doesn't have to be in the Masters to get sprains and strains

'Soma' Compound helps relieve pain and relax muscle in many musculoskeletal disorders. Patient comfort can be increased and recovery time shortened.

Soma® Compound

carisoprodol 200 mg., phenacetin 160 mg., caffeine 32 mg.

rational combination therapy for most patients with strains and sprains: relaxes muscle, relieves pain

Also available as 'Soma' Compound with Codeine: carisoprodol 200 mg., phenacetin 160 mg., caffeine 32 mg., codeine phosphate 16 mg. (Warning: may be habit-forming.)

(Warning: Codeine may be habit-forming.) **Indications:** 'Soma' Compound and 'Soma' Compound with Codeine are useful for relief of pain and stiffness in traumatic, rheumatic and other conditions affecting muscles and joints. **Contraindications:** Allergic or idiosyncratic reactions to carisoprodol, phenacetin, or codeine phosphate. **Precautions:** *Phenacetin*—With long-term use, give cautiously to patients with anemia and cardiac, pulmonary, renal or hepatic disease. May damage the kidneys when used in large amounts or for long periods. *Caffeine*—Not recommended for persons extremely sensitive to its CNS stimulating action. *Codeine phosphate*—Use with caution in addiction-prone individuals. *Carisoprodol*—Carisoprodol, like other central nervous system depressants, should be used with caution in patients with known propensity for taking excessive quantities of drugs and in patients with known sensitivity to compounds of similar chemical structure, e.g. meprobamate. **Side effects:** Drowsiness, lightheadedness, dizziness, and gastric complaints have been reported infrequently for either or both of these preparations. *Phenacetin*—Side effects are extremely rare with short-term use of recommended doses. Prolonged ingestion of overdoses may produce dyspnea, cyanosis, hemolytic anemia, skin rash, anorexia, subnormal temperature, insomnia, headache, mental disturbances, and tolerance. *Caffeine*—Side effects are almost always the result of overdosage. Average doses may rarely cause nausea, nervousness, insomnia, and diuresis. Excessive dosage may produce, in addition, restlessness, nervousness, tolerance, tinnitus, tremors, scintillating scotomata, tachycardia, and cardiac arrhythmias. *Codeine phosphate*—Possible side effects are nausea, vomiting, constipation, and miosis. *Carisoprodol*—The only side effect reported with any frequency is sleepiness, usually on higher than recommended doses. An occasional patient may not tolerate carisoprodol because of an individual reaction, such as a sensation of weakness. Other rarely observed reactions have included dizziness, ataxia, tremor, agitation, irritability, headache, increase in eosinophil count, flushing of face, and gastrointestinal symptoms. One instance each of pancytopenia and leukopenia, occurring when carisoprodol was administered with other drugs, has been reported, as has an instance of fixed drug eruption with carisoprodol and subsequent cross-reaction to meprobamate. Rare allergic reactions, usually mild, have included one case each of anaphylactoid reaction with mild shock and angioneurotic edema with respiratory difficulty, both reversed with appropriate therapy. In cases of allergic or hypersensitivity reaction, carisoprodol should be discontinued and appropriate therapy initiated. Suicidal attempts may produce coma and/or mild shock and respiratory depression. **Dosage:** Usual adult dosage of 'Soma' Compound or 'Soma' Compound with Codeine is one or two tablets three times daily and at bedtime. **Supplied:** 'Soma' Compound, orange tablets, each containing carisoprodol 200 mg., phenacetin 160 mg., and caffeine 32 mg. 'Soma' Compound with Codeine, white capsule-shaped tablets, each containing carisoprodol 200 mg., phenacetin 160 mg., caffeine 32 mg., and codeine phosphate 16 mg. Narcotic order form required. *Before prescribing, consult package circular.*

In Memoriam

A dislike of death is no proof of the want of religion. The instincts of nature shrink from it, for no creature can like its own dissolution. — But though death is not desired, the result of it may be, for dying to the Christian is the way to life eternal. — W. Jay

DALE D. TURNACLIFF

Dr. Dale D. Turnacliff, 76, of St. Paul, died December 29th. He had maintained a private medical practice and had worked as medical director of the former Twin City Rapid Transit Company for thirty-six years until his retirement from the post in 1948. Dr. Turnacliff had offices in the Minneapolis Medical Arts building where he specialized in dermatology.

He was born in Waseca County and graduated from the University of Minnesota medical school. He was a member of the Hennepin County Medical Society and the American Medical Association and an associate and 50 Club member of the Minnesota State Medical Association.

He is survived by his wife, a daughter, and a son, Dr. Robert D. Turnacliff, Palos Verdes Estates, California.

J. ANTHONY MALERICH

Dr. J. A. Malerich, 73, St. Paul surgeon, died January 16th. Born in Arlington, Dr. Malerich had practiced medicine in Richardton, North Dakota, Shakopee, Caledonia and fifteen years in West St. Paul before he retired in 1958.

He was a member of the American Academy of General Practice, American Medical Association, Ramsey County Medical Society, an associate fellow of the International College of Surgeons, and an associate member of the Minnesota State Medical Association.

Dr. Malerich is survived by his wife, three daughters, and a son, Dr. J. A. Malerich, Jr. of West St. Paul.

OTTO W. YOERG

Dr. Otto W. Yoerg, 78, retired Minneapolis surgeon, died January 27th. He was a graduate of the University of Minnesota Medical School and a member of the staff of Northwestern hospital for forty years. He was chief surgeon for many years for the Milwaukee Road; Rock Island Lines and Chicago Great Western Railway Co. and a former president of the Minneapolis Surgical Society. He was also a member of the American College of Surgeons and the Academy of Medicine.

Dr. Yoerg was a member of the Hennepin County Medical Society and American Medical Association and a 50 Club and life member of the Minnesota State Medical Association.

He is survived by his wife.

CARL G. BURTON

Dr. Carl G. Burton, 70, prominent St. Paul East Side physician, died January 18th. He was born in Ljungby, Sweden, and came to St. Paul in 1914. He was a graduate of the University of Minnesota Medical School.

Dr. Burton was on Bethel college's board of education for seventeen years, was recently made an honorary member of the Mounds Park Hospital, was a member of the Ramsey County Medical Society, American Medical Association and an associate member of the Minnesota State Medical Association.

He is survived by his wife, and two sons, one of whom is Dr. J. Richard Burton of St. Paul.

Better Service, Doctor?

I DON'T FEEL GOOD!

Yes, Blue Shield wants to serve Minnesota doctors even better than it has. But we need your help.

When reporting claims, list symptoms for diagnostic laboratory and X-ray services ONLY. We do not need symptoms for any other service.

And, there must be a *direct* connection between those symptoms and the tests.

Payment for incomplete reports might be delayed . . . or rejected. Help us help you!

SIGNEMYCIN®

Side Effects: Glossitis and allergic reactions, as well as severe anaphylactoid reactions, have been reported as rare side effects. Should significant reaction or idiosyncrasy occur, discontinue medication and institute countermeasures. Use of tetracycline during the last trimester of pregnancy, neonatal period and early childhood may cause discoloration of developing teeth. Reduce usual oral dosage and consider serum level determinations in patients with impaired renal function to prevent possible liver toxicity due to excessive accumulation of antibiotic in the serum.

Precautions: Overgrowth of nonsusceptible organisms may occur. In such cases, discontinue medication and institute appropriate specific therapy as indicated by susceptibility testing. Aluminum hydroxide gel given with antibiotics has been shown to decrease their absorption and is contraindicated. The coloring agents used in Signemycin Syrup and Pediatric Drops may produce red discoloration of stools.

Triacetyloleandomycin, a constituent of Signemycin, administered to adults in daily oral doses of 1.0 Gm. (3 Gm. Signemycin) for periods of more than ten days may produce hepatic dysfunction and jaundice. In the rare patient who requires this high dosage level of Signemycin initially, liver function should be carefully followed and dosage should be reduced, as promptly as possible, to the usual recommended range of 1.0 to 2.0 Gm. per day. Therefore, Signemycin is recommended primarily for the treatment of acute or severe infections, with treatment restricted to a ten-day period. If clinical judgment dictates continuation of therapy beyond ten days, serial monitoring of the liver profile should be carried out, including BSP, transaminase, and cephalin flocculation tests. Changes observed in liver function were reversible following discontinuation of the drug.

Formulas: Capsules: 250 mg. Signemycin (167 mg. tetracycline HCl and 83 mg. oleandomycin as triacetyloleandomycin).

Capsules: 125 mg. Signemycin (83 mg. tetracycline HCl and 42 mg. oleandomycin as triacetyloleandomycin).

Syrup: 125 mg. Signemycin (tetracycline equivalent to 83 mg. tetracycline HCl and 42 mg. oleandomycin as triacetyloleandomycin) per 5 cc.

Pediatric Drops: 100 mg. Signemycin (tetracycline equivalent to 67 mg. tetracycline HCl and 33 mg. oleandomycin as triacetyloleandomycin) per cc.

More detailed professional information available on request.

Science for the world's well-being® Pfizer *Since 1849*

PFIZER LABORATORIES Division, Chas. Pfizer & Co., Inc. New York, New York 10017

® **Of 5,057 patients with confirmed infections of all body systems... 4,731 or 93.5% were treated successfully with Signemycin®**

Note:

The high rate of response to Signemycin in these cases is noteworthy because the totals include many patients with difficult-to-treat infections, many whose infections had proved resistant to other agents, and many who had been treatment failures on other therapy.[1-87] In addition the following criteria were used for the cases cited: (1) only published results were used (2) results were confirmed by clinical and/or laboratory findings (3) patients were cured, not "improved" (4) dosage conformed with current recommendations in the United States (5) no other anti-infective agents were used concomitantly (6) no instance of prophylactic use was included in these tabulations.

Condition	No. of Patients	No. Responded To Signemycin
Ear, nose and throat infections	507	465
Respiratory infections	1,028	954
Gastrointestinal infections	425	387
Genitourinary infections	748	684
Skin and soft-tissue infections	1,088	1,036
Bone and joint infections	71	64
Deep-seated or generalized infections	257	251
Obstetrical & gynecological infections	341	320

GENERAL PRACTITIONER WANTED: Lamberton, Minnesota. Nearly new Sears Roebuck Foundation designed clinic available. Excellent school, churches and community. Call or write: Wallace Nelson, Lamberton, Minnesota, 56152, Telephone 752-7717.

WANTED: Associate for a general practice, leading to partnership. Previous partner entered specialty training January 1st. Position available anytime. Excellent working conditions. Salary open. Contact: C. R. Peluso, M.D., 938 Lowry Avenue N.E., Minneapolis.

FOR SALE: Clinic and hospital equipment in excellent condition: Hamilton examining tables, treatment and instrument cabinets, examining chairs, Castle floor lamps, sterilizers, eight hospital beds, bedside tables, limited surgical and fracture equipment, Microtherm, ultra sound unit, X-ray cassettes, filing cabinets, refraction equipment, etc. Write: MINNESOTA MEDICINE — 301; 496 Lowry Medical Arts Building, St. Paul, 55102.

WANTED LOCUM TENENS: Three man Minneapolis GP group desires M.D. with Minnesota License to work during all or some parts of the Spring and Summer months. Salary open. JA 9-9251 — Minneapolis.

MEDICAL CLINIC: Completely equipped air-conditioned medical clinic including X ray. Has seven examining rooms, X-ray room and lab. Two offices, waiting room, dental clinic including lab. Brick building 70x45 on ground level. An excellent St. Paul-Minneapolis location. Will sell or lease with option to buy. A great opportunity. Call or write: Birney J. Novotny, CA 4-2346 or 712 Northwestern Bank Bldg.; St. Paul, 55102.

WHITE BEAR LAKE, MINNESOTA: A suburban community of 35,000 and growing fast. Have available several ground floor air-conditioned suites in fireproof building in central business district, free municipal parking lot at second entrance in rear. See N. R. Dittberner, 316 Washington Avenue, White Bear Lake. Telephone Collect any time — 429/7787.

PRACTICE FOR SALE: California, San Diego County. General practice. Five-year average gross over $60,000. Modern office for lease. Full equipment included in the sale. No cash necessary. Open district hospital. Write: MINNESOTA MEDICINE — 302; 496 Lowry Medical Arts Building, St. Paul, 55102.

The Blue Shield

New Minneapolis Director

Dr. Charles A. Neumeister, a Minneapolis physician, has been elected to the board of directors of Blue Shield. He replaces Dr. C. A. McKinlay, who resigned for reasons of health.

Dr. Neumeister is a member of the House of Delegates of the American Medical Association, fellow of the American College of Surgeons and fellow of the American Proctologic Society.

Dr. McKinlay was honored by the Blue Shield board in a special resolution to express "appreciation and esteem for him as one of the original members of the Board of Directors."

Dr. McKinlay had served Blue Shield since January 4, 1947.

Living Science Library

Blue Shield has provided the Saint Paul Science Museum with a collection of science teaching aids called The Blue Shield Living Science Library.

The Library is designed to aid young students to delve deeper into the biological sciences and encourage them to a career in Medicine.

The Blue Shield collection consists of more than 30 science teaching aids and models ranging from microscopes to life-size, take-apart models of the human anatomy. The equipment is now being used by the Science Museum in its formal teaching program for bright young science students.

The guest speaker for the opening session was Joseph Mayo, managing curator of the Duluth Zoo and grandson of the founders of the Mayo Clinic.

New 'Senior Citizen' Plan

Blue Shield's new Senior Citizen program, introduced last fall, is continuing to attract subscribers. The coverage is available to persons age 65 and older and offers the combination of medical-surgical as well as hospital and nursing home coverage.

The hospital portion of the program offers 90 days of care per year for each separate illness. The plan has no dollar limit on the cost of hospital "extras," but to hold down premium costs, the payment is on an 80/20 basis. Two options are offered for hospital room costs, either $15 or $10 per day.

The medical-surgical portion of the program is the standard and well-proven Blue Shield Citizen contract. It offers in-hospital medical care benefits for up to 120 days as well as benefits for generally accepted surgical procedures. In addition, the program provides anesthesia coverage as well as outpatient diagnostic laboratory and X-ray benefits.

Today, Blue Shield provides coverage for about 75,000 Minnesota Senior Citizens.

Training Sessions

Blue Shield's "service seminars," designed to help doctors' assistants give better service to subscribers, will continue through 1965.

The seminars focus attention on ways to speed claim processing, tell about various coverages and give special emphasis on new ways to give better service to area residents.

A portion of the program is reserved for questions so that individual attention can be given to any special problems encountered by assistants.

The training sessions, now in their third year, have met with considerable success. The over-all effect is speedier and more complete flow of information from the doctor's office to Blue Shield. In turn, this is rewarded by faster payment of claims, less paperwork, better satisfied patients and Blue Shield subscribers.

Every man is a damn fool for at least five minutes every day; wisdom consists in not exceeding the limit. — Elbert Hubbard

=a tranquilaxant

Rx

TRANCOPAL®

BRAND OF

CHLORMEZANONE

Trancopal "is effective in symptomatic treatment of anxiety."* A powerful tranquilaxant, it also relieves muscle spasm so often accompanying anxiety and tension. Other indications include: ulcer syndrome, spastic colon, alcoholism, premenstrual tension, and bronchial asthma. Side effects such as occasional drowsiness, dizziness, flushing, nausea, depression, weakness and drug rash have been observed in less than 3 per cent of patients. If severe, medication should be discontinued. In most patients, side effects are minor and do not necessitate interruption of treatment. There are no known contraindications. The usual adult dosage is one Caplet® (200 mg.) three or four times daily; in some patients 100 mg. three or four times daily suffice. Dosage for children (5 to 12 years) is usually from 50 to 100 mg. three or four times daily. Trancopal is available in 200 mg. Caplets (green colored, scored) and 100 mg. Caplets (peach colored, scored).

Tension complicated by pain?

...you want a dependable tranquilaxant plus the analgesic effect of aspirin

Rx

TRANCO-GESIC*

CHLORMEZANONE 100 mg. **with ASPIRIN** 300 mg.

TRANCO-GESIC...for the more comprehensive control of pain, especially in tension headache, sciatica, lumbago and musculoskeletal pain associated with strains or sprains...acts dependably and with unsurpassed tolerance. Contraindicated in persons known or suspected to have an idiosyncrasy to aspirin. Side effects such as gastric distress, occasional weakness, sedation or dizziness may be noted occasionally. Ordinarily, these may be reversed by a reduction in dosage or temporary withdrawal of the drug. The usual adult dosage is 2 tablets three or four times daily. The suggested dosage for children from 5 to 12 years is 1 tablet three or four times daily.

Hygroton®
brand of chlorthalidone
the long-acting diuretic

Geigy

Indications: Many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity, and most cases of severe renal or hepatic disease.
Precautions: Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Side Effects: Constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, leukopenia, muscle cramps, nausea, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.
Average Dosage: One tablet (100 mg.) daily with breakfast.
Availability: Tablets of 100 mg. in bottles of 100 and 1000.
For full details, see the complete prescribing information.

epilepsy can undermine self-reliance

"A therapeutic 'bull's-eye' may be scored with DILANTIN [diphenylhydantoin] even for a person with long-standing convulsions previously unrelieved by phenobarbital."* Such efficacy can make a substantial contribution to your epileptic patient's rehabilitation...improve his prospects for employment...foster greater self-reliance.

Indications: Grand mal epilepsy and certain other convulsive states. **Precautions:** Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. **Side Effects:** Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Upon discontinuation of therapy eruptions usually subside. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Though mild and rarely an indication for stopping dosage, gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered, especially in children, adolescents, and young adults. During initial treatment, minor side effects may include gastric distress, nausea, weight loss, transient nervousness, sleeplessness, and a feeling of unsteadiness. All usually subside with continued use. Hematologic disorders including megaloblastic anemia, leukopenia, granulocytopenia, pancytopenia, and aplastic anemia have been reported. Nystagmus may develop. DILANTIN is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm.

BSP® DISPOSABLE UNIT

H.W.&D. BRAND OF SULFOBROMOPHTHALEIN SODIUM INJECTION, U.S.P.

(50 mg. per ml.)

Bromsulphalein (BSP), one of the most sensitive diagnostic agents for evaluating liver function, is now available in a new Disposable Unit. Each "unit" contains: A sterile BSP syringe calibrated in milliliters and pounds (utilizing the 5 mg./kg. BSP dosage schedule), a sterile disposable needle, alcohol swab and a 7.5 or 10 ml. size ampule of BSP.

The precalibrated dosage schedule imprinted on the syringe barrel makes weight calculations unnecessary—saving time and assuring proper administration of the dye, regardless of patient-weight.

Literature on indications and dosage available on request.

The NEW BSP DISPOSABLE UNIT is supplied in 7.5 and 10 ml. sizes in boxes of 10's and 25's.

disability without debilitation...

supportive oral anabolic therapy • potent • well-tolerated

Disabling illness or injury at any time of life can invite a slowdown in the natural anabolic processes or acceleration of catabolic processes, resulting in a "wasting" of protein and minerals needed for tissue repair. Loss of weight and appetite, strength and vitality, may be the evident signs of this process, frequently accompanied by a lowering of mood, interest and activity. The older the patient, the more pronounced may be the signs of debilitation. A potent, well-tolerated anabolic agent plus a diet high in protein can make a remarkable difference.

WINSTROL® brand of **STANOZOLOL**

...a new oral anabolic agent, combines high anabolic activity with outstanding tolerance. Although its androgenic influence is extremely low*, women and children should be observed for signs of slight virilization (hirsutism, acne or voice change), and young women may experience milder or shorter menstrual periods. These effects are reversible when dosage is decreased or therapy discontinued. Patients with impaired cardiac or renal function should be observed because of the possibility of sodium and water retention. Liver function tests may reveal an increase in BSP retention, particularly in elderly patients, in which case therapy should be discontinued. Although it has been used in patients with cancer of the prostate, its mild androgenic activity is considered by some investigators to be a contraindication.

Dosage in adults, *usually 1 tablet t.i.d.;* young women, *1 tablet b.i.d.;* children (school age), *up to 1 tablet t.i.d.;* children (pre-school age), *½ tablet b.i.d. Shows best results when administered with a high protein diet. Available as scored tablets of 2 mg. in bottles of 100.*

*The therapeutic value of anabolic agents depends on the ratio of anabolic potency to androgenic effect. This anabolic–androgenic activity ratio of Winstrol is greater than that of all the oral anabolic agents currently in use.

GENERAL INFORMATION

Authors

Manuscripts for consideration in Minnesota Medicine should be addressed to Office of Publication, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Papers should be typed double spaced on white paper with a wide margin. The first page should list the title, the name of the author (or authors), degree, and any institutional or other credits. Pages should be numbered consecutively. Tables should be typed and numbered and should have a brief descriptive caption.

Bibliographical references should be limited to twelve and should be typed in conformity to the method used by the Index Medicus. They should be numbered consecutively in the order in which they first appear in the text. Book references should give the name of the author, title, edition number, publisher, and the year.

Illustrations (photographs, tables, and graphs) should be submitted on separate sheets of paper and not combined in the text. Instructions for combining photographs are acceptable.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

in maintenance therapy... a working analgesic for the active arthritic

ARTHRALGEN®

Each tablet contains:

Salicylamide	250 mg.
Acetaminophen	250 mg.
Ascorbic acid (Vitamin C)	25 mg.

a working analgesic for the active arthritic

—rapidly relieves early morning stiffness and arthritic pain. It promises a quicker response in most patients because its analgesic ingredients need no metabolic conversion before they act. As a combination of two prominent analgesic drugs, Arthralgen can often establish smoother, more complete pain relief because it synergistically produces more efficient analgesia on lower dosage levels of each.

two proven pain relievers

Arthralgen combines two better-tolerated, time-tested analgesics, acetaminophen and salicylamide, into a pharmacologically sound and therapeutically effective formulation. As Arthralgen, it penetrates tissues promptly and relieves pain rapidly with less likelihood of gastric irritation than aspirin.

sodium-free

Arthralgen contains no sodium. Therefore, it is often a safer and more suitable analgesic for use in the long-term treatments of arthritic patients who have other conditions which require sodium restriction.[1]

ARTHRALGEN®-PR (Arthralgen with prednisone)

Each tablet contains:

Salicylamide	250 mg.
Acetaminophen	250 mg.
Ascorbic acid (Vitamin C)	25 mg.
Prednisone	1 mg.

To help provide dosage flexibility in patients who require steroids, the basic Arthralgen formula is also available combined with prednisone as Arthralgen-PR. Prednisone is favored as the more advantageous steroid for use in Arthralgen-PR because it shows less tendency toward sodium retention, potassium excretion, and steroid-induced hypertension than that which often accompanies the use of cortisone and ACTH.[2]

A. H. ROBINS COMPANY, INCORPORATED/RICHMOND, VIRGINIA

BRIEF SUMMARY

Arthralgen and Arthralgen-PR are indicated in the management of rheumatoid arthritis, acute gouty arthritis, rheumatoid spondylitis, osteoarthritis, bursitis, fibrositis, and neuritis. Arthralgen may be used for analgesia in colds, flu, and various myalgias.

DOSAGE: One or two tablets four times a day. After remission of symptoms dosage should be reduced to the minimum maintenance level.

SIDE EFFECTS: Nausea, GI upset, or mild salicylism may rarely occur. Symptoms of hypercorticoidism dictate reduction of dosage of Arthralgen-PR.

PRECAUTION: Reduction in dosage of Arthralgen-PR given over a long period should be gradual, never abrupt.

CONTRAINDICATIONS: Hypersensitivity to any ingredient.

As with any drug containing prednisone, Arthralgen-PR is contraindicated, or should be administered only with care, to patients with peptic ulcer, tuberculosis, nephritis, diabetes mellitus, acute psychoses, Cushing's syndrome (or Cushing's disease), overwhelming spreading (systemic) infection, or predisposition to thrombophlebitis.

Arthralgen-PR is generally contraindicated in patients with uremia and viral infections, including poliomyelitis, vaccinia, ocular herpes simplex, and fungus infections of the eye. It is also contraindicated in patients with chicken pox or susceptible persons exposed to it.

SUPPLY: Arthralgen (white, scored) and Arthralgen-PR (yellow, scored) tablets are available in bottles of 100 and 500.

REF: 1. Boreus & Sandberg, ACTA. PHYSIOL. SCAND., 28:266, 1953. 2. Cohen, et al.: J.A.M.A., 165:225, 1957.

President's Letter

At a special meeting in February, the House of Delegates of the American Medical Association voted to support the Herlong-Curtis bill (HR 3727), which would encourage the use of voluntary health insurance and prepayment plans in the implementation of Kerr-Mills programs for persons more than 65 years old. This bill, which the AMA has called "Eldercare," would permit a state to have a health-oriented agency supervise or adminster the program which provides for a wide spectrum of medical care in which a citizen more than 65 years of age would pay all, part or none of the cost, depending on his income. An income-information statement serving as the sole eligibility test of need is proposed. I suggest that you study the more detailed explanations of this bill so that you may support it in a knowledgeable way. At the special meeting the delegates also asked the Board of Trustees to study the "desirability and feasibility of extending the principle of federal and state aid under the Kerr-Mills principle to persons below the age of 65 who need help." They also urged that the professional services of pathologists, radiologists, physiatrists, and anesthesiologists be excluded from any bill which excludes other physicians' services. In whatever way hospital services may be provided, the methods suggested in Eldercare for the payment of physicians' services are sound.

In the past few years, many resolutions which concern the economic aspects of medical care have been introduced in the AMA House of Delegates. At the present time, specialist societies, particularly those associated with the American Society of Internal Medicine, are preparing plans to be discussed. Many physicians are asking that organized medicine give more attention to planning for an adequate method of protection against catastrophic expense in medical care. One theme in common with Eldercare which runs through most of the proposals is the use of voluntary private insurance and prepayment plans. With the AMA leading the way, physicians will place great emphasis on this mechanism in their thinking for the future, and it is obvious that interest and cooperation of the insurance industry and the Blue Shield and Blue Cross plans will be necessary. It is reported that Blue Shield has shown the greatest interest in the latest proposals. We recall that nearly 30 years ago, it was the Doctors' Plan, Blue Shield, which led the way in helping physicians accomplish their goal of protection against medical costs of the low income group. Perhaps Blue Shield will again be a leader, which emphasizes that at both national and states levels there must be the closest cooperation between medical societies and the Blue Shield organization so that Blue Shield will be, in fact, the Doctors' Plan. It is my hope that the report of the Minnesota House of Delegates ad hoc committee to study Minnesota Blue Shield will have acceptable suggestions for cementing closer liaison between our medical association and Minnesota Blue Shield.

PULVULES'
ILOSONE'
ERYTHROMYCIN ESTOLATE
CAPSULES, U.S.P.
250 mg.
CAUTION—Federal (U.S.A.) law prohibits dispensing without prescription.
Keep Tightly Closed
ELI LILLY AND CO., Indianapolis, U.S.A.

Test-tube activity of a drug is only one indication of its effectiveness. More important is the amount of antibacterial activity at the site of infection.

Ilosone® produces peak levels of antibacterial activity *two* to *four* times those of other erythromycin preparations. Furthermore, it attains them earlier and maintains them longer.

Contraindications: Ilosone is contraindicated in patients with a known history of sensitivity to this drug and in those with preexisting liver disease or dysfunction.

Side-Effects: Even though Ilosone is the most active oral form of erythromycin, the incidence of side-effects is low. Infrequent cases of drug idiosyncrasy, manifested by a form of intrahepatic cholestatic jaundice, have been reported. There have been no known fatal or definite residual effects. Gastro-intestinal disturbances not associated with hepatic effects are observed in a small proportion of patients as a result of a local stimulating action of Ilosone on the alimentary tract. Although allergic manifestations are uncommon with the use of erythromycin, there have been occasional reports of urticaria, skin eruptions, and, on rare occasions, anaphylaxis.

Dosage: *Children under 25 pounds*—5 mg. per pound of body weight every six hours. *Children 25 to 50 pounds*—125 mg. every six hours. *Adults and children over 50 pounds*—250 mg. every six hours. For severe infections, these dosages may be doubled.

Available in Pulvules®, suspension, drops, and chewable tablets. Ilosone Chewable tablets should be chewed or crushed and swallowed with water.

Ilosone®
Erythromycin Estolate

Orthostatic Hypotension*

S. SCOTT NICHOLAS, M.D.**
Minneapolis, Minnesota

IN 1925 Bradbury and Eggleston[1] described postural hypotension as a syndrome; patients so affected experienced a fall in blood pressure to hypotensive levels whenever they assumed the upright position. The original report included three cases; subsequently many more cases have been reported and the condition is well documented.[2] The syndrome, orthostatic hypotension, is manifested by the following:

1. The heart rate remains fixed when the patient assumes the upright position (noted in about 50% of instances); 2. Various degrees of anhidrosis (occurs in about 33%); 3. A low basal metabolic rate; 4. An elevated blood urea level; 5. Slight and variable signs of central nervous system disease; 6. Nocturnal polyuria; 7. Occasionally anemia.

The anhidrosis is said to begin as a stocking-and-glove type of distribution and may eventually involve the whole body, usually sparing the face. The neurologic deficits that may be observed include increased deep tendon reflexes, reduced ability to perform alternating motion of the hands and feet, mask-like facies, tremor, muscular rigidity suggestive of Parkinsonism and positive Babinski reflexes. In some patients slurring of the speech and a decrease in intellectual faculties are noted.

Etiologic Factors

Among the various pathological processes that can cause orthostatic hypotension are Addison's disease, central neuropathic conditions (e.g., syringomyelia, tabes, Parkinsonism, etc.), and autonomic neuropathies. These must be considered in the differential diagnosis and be excluded by appropriate studies; circulatory disturbances induced by hypovolemia or by hypokalemia must likewise be excluded. Idiopathic orthostatic hypotension is probably an autonomic neuropathy.[2] Most of the evidence now available incriminates the neuroeffector junction of the sympathetic nerve fibers in the vascular bed.[3,4] It is felt that there is a failure of release of norepinephrine at this level, and there is clinical evidence to suggest that the parasympathetic component may also be involved.[4] For example, massage over the carotid artery fails to lower the arterial pressure and elevate the pulse rate in some patients. In others a lack of response of gastric secretion to insulin-induced hypoglycemia has been observed. It is felt that these findings indicate defective parasympathetic system function.

Treatment

The approach to the treatment of orthostatic hypotension has followed three main lines: mechanical devices, vasoconstrictive agents and extracellular fluid expanders. The first involves the use of such devices as abdominal support, elastic stockings and even pressure suits. Secondly, various vasoconstrictors or pressor drugs such as ephedrine and vasopressin have been employed, the latter given as the tannate in oil or by nasal inhalation of the whole posterior pituitary extract.

Extracellular Fluid Expanders

Gregory[5] was the first to employ a drug designed to expand the extracellular fluid balance in a patient with idiopathic orthostatic postural hypotension. In 1945, he reported on the effective use of desoxycorticosterone. The treatment was successful, but the method of administration was somewhat cumbersome because injections of desoxycorticosterone suspended in oil were required three times a week. Because of the similarity of its action to desoxycorticosterone, 9 alpha-fluoro-hydrocortisone was suggested for the treatment of postural hypotension due to autonomic dysfunction.[6] This substance is a potent salt-retaining mineral corticoid with weak antiphlogistic activity. It can be administered orally. In 1959, two cases successfully treated with low doses of this preparation were reported.[6] Wagner,[2] in his 1959 review, cited the case of a 21-year-old patient, severely incapacitated by the disease, who had been treated successfully with this preparation for the preceding three years. In 1962, Schrager et al. reported the use of this preparation in six patients.[7] The symptoms caused by the hypotension were successfully controlled in all but one patient. The neurological symptoms that are occasionally seen with this syndrome are not helped by 9 alpha-fluoro-hydrocortisone.

Case Report

A 73-year-old white male first presented to this hospital on July 3, 1962. He had experienced episodes of weakness and dizziness during the preceding five years; these had become much worse in the previous two weeks. He had become almost totally incapacitated by the dizziness which manifested itself primarily in the morning. Upon arising from the supine or sitting position, he would become extremely "lightheaded" and on several occasions fell. However, he never totally lost consciousness. The symptoms tended to abate toward the late afternoon. The patient's wife had noted that his hearing acuity had decreased and that he could hear words but often could not interpret them (receptive aphasia.)

The patient had been evaluated at another hospital where the diagnosis of postural hypotension was confirmed. Conventional therapeutic attempts failed and the patient was referred to Hennepin County General Hospital.

Physical Examination

Physical examination revealed an elderly, healthy-appearing white male. His blood pressure and pulses were as follows: supine: 140/90 — pulse 90/min.; sitting: 90/60 — pulse 100/min.; standing: 50/30 — pulse 110/min. He was oriented in all spheres but was noted to have very slow mentation and difficulty in expressing himself. He had a mask-like facies and an intention tremor without other evidence of rigidity. The remainder of the neurological and physical examination was unremarkable.

Laboratory Observations

Laboratory results at this time revealed: hemoglobin, 11.7 gm.% (subsequently 13 gm.% after two months of iron therapy); wbc 7700 (70% PMN's, 27% lymphocytes, 3% monocytes); urinalysis: cloudy, yellow, sp. gr. 1.014, albumin, sugar and cellular elements absent; fasting blood sugar 91 mgm.% per 100 ml.; and blood urea nitrogen, 30 mgm.% per 100 ml. A chest X ray showed no evidence of active disease and an electrocardiogram was normal. A glucose tolerance test revealed levels of 303, 80 and 90 mg. per 100 ml. at one, two and three hours respectively. Electrolytes were as follows: CO_2 combining power, 29 m.Eq/L; clorides, 90 m.Eq/L; sodium, 142 m.Eq/L; potassium, 4.75 m.Eq/L.

Treatment

Treatment for the postural hypotension initially consisted of an abdominal binder, elastic bandages for the legs, and ephedrine by mouth. No improvement was obtained in the next six weeks. Subsequently dexedrine and methyl testosterone were used without benefit. These medications were then discontinued and a trial of 9 alpha-fluoro-hydrocortisone (Florinef®) was undertaken. Beneficial results were almost immediate and striking. The patient again became self-sufficient, able to dress himself, help around the house and go for long walks. His blood pressures after the first four days of therapy were: 108/58 (sitting) and 104/54 (standing). Initially there was a slight fluid retention and diuretics were required. Throughout the period of observation the electrolytes were stable (see Table).

Progress

Six weeks after the commencement of therapy the supine blood pressure was elevated, 160/110; the dose of the steroid was lowered. The adjustments in dosage are indicated in the Table. During the first six months of treatment, the patient complained of morning headaches; these were relieved by salycilates and to some degree by elevating the head of the bed. At first the elevated supine blood pressure caused some concern as did the gradual weight gain. Since the peripheral edema was only moderate, it was felt that much of the weight gain was due to improved food intake rather than to fluid accumulation.

The following regimen was finally established: 0.1 mgm. of Florinef® b.i.d. six days a week, 0.1 mgm. on the other day (Tuesday); 50 mgm. of hydrochlorthiazide one day each week (Friday), and supplemental potassium chloride, 1.0 gm. daily. An antacid was given twice daily. On this regimen the patient's weight remained relatively stable and the blood pressure when supine remained fairly constant at 170/90-100 mm. of mercury. The problem of both postural hypotension and hypertension was minimized. After six months of observation on this regimen the patient returned to the care of his private physician. The latter reported that the patient's mental status had continued to deteriorate but the blood pressure and serum electrolytes remained at comparable levels (Mar. 2, 1964, see Table). It is of interest that the symptoms of hypotension tended to recur, in a mild form, on the day following the administration of the diuretic agent. The patient's neurological symptoms were unaffected by the therapeutic program. Schrager et al.[7] have observed similar trends in their patients.

Discussion

In patients responding favorably to 9 alpha-fluoro-hydrocortisone, the supine blood pressure is moderately elevated over pretreatment levels. The pressure still falls more than would be considered normal when the individual stands or sits; but the drop in pressure is less marked than before treatment and the undesirable symptoms of postural hypotension do not occur.

*data supplied by private physician

Clinical observations in a patient exhibiting orthostatic hypotension.

Florinef® (9 alpha-fluoro-hydrocortisone) is a potent mineral corticoid. For this reason, it was hypothesized that its therapeutic effect in idiopathic orthostatic hypotension may be due to an expanded intravascular fluid volume.[6,8] It has also been suggested[6] that the sodium retention induced by this corticoid stimulated the posterior pituitary to secrete increased amounts of vasopressin. However, Schrager et al.[7] showed that there was no *sustained* change in serum electrolytes, body space measurements, or exchangeable sodium or potassium. Their studies indicated that an acute expansion of the extracellular fluid with some sodium retention did occur, but on a long-term basis these changes tended to correct themselves. These investigators also measured urinary and plasma corticoid levels in patients under treatment and failed to find evidence for a suppression of adrenal cortical function.

Thus it would appear that the therapeutic effect of 9 alpha-fluoro-hydrocortisone is related in some way to its influence on sodium metabolism, but the exact mechanism involved is not clear.

Summary

A case of idiopathic orthostatic hypotension was effectively treated with 9 alpha-fluoro-hydrocortisone.

The mechanism by which 9 alpha-fluoro-hydrocortisone exerts a favorable effect is as yet not satisfactorily explained.

The Use of Total Starvation in the Management of Chronic Obesity*

ALVIN L. SCHULTZ, M.D.**
LAURA A. WERNER, B.S.
AARON KERLOW, M.D.†
Minneapolis, Minnesota

PERIODS OF total starvation have been suggested in the treatment of chronic intractable obesity.[1,2] Obese patients have been totally fasted for as long as 117 days without serious side effects.[3] It is now apparent that the obese person who does not respond to hypocaloric diets will consistently lose weight when placed on total caloric deprivation. The present investigation was undertaken to determine the effect of starvation on adrenal cortical function.[4] However, observations were also made on the general effects of starvation in obese subjects, and these results are reported here.

Materials and Methods

Material

Seventeen obese human subjects were obtained as volunteers from among patients attending the Mount Sinai Hospital Outpatient Clinics. Fourteen were women and three were men, ranging in age from 14 to 64 years, and in weight from 188 to 317 lbs. The age, height, ideal and actual weights of each subject are shown in Table 1. None had clinical signs of adrenal cortical hyperfunction, diabetes mellitus, or significant disease other than marked obesity. All had been obese for many years and unable to reduce their weight through hypocaloric diets. Each patient had been receiving sufficient calories to maintain weight stable for at least two weeks prior to inclusion in the study. Each was hospitalized and taken off medications during the period of study.

*This study was supported by grants from the John A. Hartford Foundation, New York, N. Y., the Minnesota Heart Association, and the General Medical Research Fund of Mount Sinai Hospital.

**Director, Department of Medicine, Mount Sinai Hospital Associate Professor of Medicine, University of Minnesota.

†Chief Medical Resident, Mount Sinai Hospital Medical Fellow, University of Minnesota Graduate School.

Measurements of adrenal cortical function, hemograms, blood urea nitrogen, fasting and post-prandial blood sugars, serum cholesterol, serum uric acid, urinalysis and electrocardiograms were made on each subject. Electroencephalograms were performed on five patients.

After obtaining the base line measurements, twelve obese women were put on total starvation for a period of 13 days. During this period, fluid intake was maintained at 2000 ml. daily in the form of water, tea, coffee, and up to three bottles of a dietary cola drink (three calories per bottle). Activity was limited to bathroom privileges and walking within their hospital rooms. At the end of the 13-day fast period, control measurements were repeated and the patients discharged from the hospital on a 1200 calorie diet.

Methods

The following measurements of adrenal cortical function were made: (1) 24-hour urinary excretion of 17-hydroxycorticosteroids (17-OHCS) and 17-ketosteroids (17-KS), (2) plasma 17-OHCS at 8:00 PM and 8:00 AM, and (3) plasma 17-hydroxycorticosteroids response to adrenocorticotrophic hormone (ACTH) (25u administered intravenously as a four-hour infusion in 500 ml. normal saline).

Plasma and urinary 17-hydroxycorticosteroids were determined by the method of Porter and Silber as modified by Peterson et al.[5] Urinary 17-ketosteroids were measured by the method of Drekter as modified by Klendshoj et al.[6] Serum uric acid was measured by the method of Kern and Stransky as modified by Archibald.[7] Plasma and urine acetone was determined qualitatively by the method of Rothera. Blood-urea nitrogen, blood sugar, and serum cholesterol were measured by standard methods.

Results

Adrenal Function Before Starvation

Measurements of adrenal cortical function in 17 obese subjects while on adequate caloric intake are shown in Table 1. Although the mean values for 8:00 PM and 8:00 AM plasma 17-hydroxycorticosteroids were within the normal range, the morning level was higher than the mean of 13 mcg% established in our laboratory for lean normal subjects. Four patients had definitely elevated values for 8:00 AM plasma 17-hydroxycorticosteroids (above 22 mcg%), and one patient (H. W.) showed no diurnal difference. The mean urinary excretion of 17-hydroxycorticosteroids and 17-ketosteroids,

and the response to ACTH were within normal limits. Two patients had elevated urinary 17-ketosteroid excretion and two had slightly elevated 17-hydroxycorticosteroid excretion.

Weight Loss During Starvation

By the end of the 13-day starvation period, the 12 obese women had lost an average of 23 lbs. per individual (Table 2). The mean weight loss per day of starvation was 1.8 lbs. (range: 1.2-2.7 lbs./day). It is apparent from Figure 1 that the daily weight loss was greater during the first week of starvation than during the second.

Side Effects of Starvation

Most of the patients complained of hunger during the first 24-36 hours of fasting. However, hunger was not a problem in any subject after the second day of starvation, even though other patients in the same room were brought food trays at meal times. The fasting subjects not only had little desire to eat, but also had to be reminded to drink fluids in order to keep their daily intake at 2000 ml. By the fourth starvation day, most of the patients had become listless and apathetic, with little interest in physical or intellectual activity. None were significantly depressed. Some complained of mild headache and all had a decreased number of stools during the starvation period. At the end of the 13-day fast, most of the patients had to be urged to resume eating, and several asked to continue on starvation for a second two-week period. There were no significant emotional disturbances or other serious side effects during or following starvation.

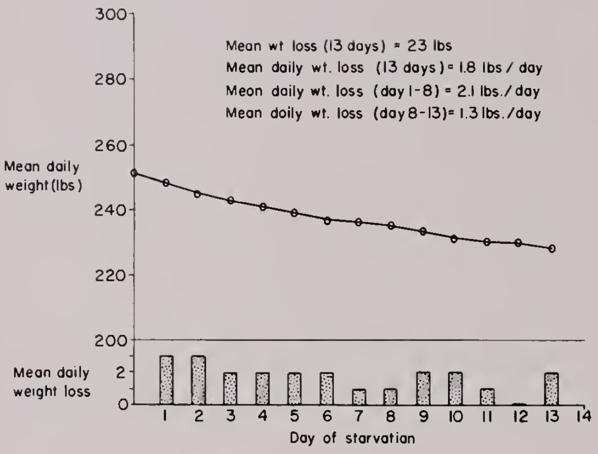

Fig. 1 — Rate of weight loss (mean values) for twelve obese women during a 13-day period of total starvation.

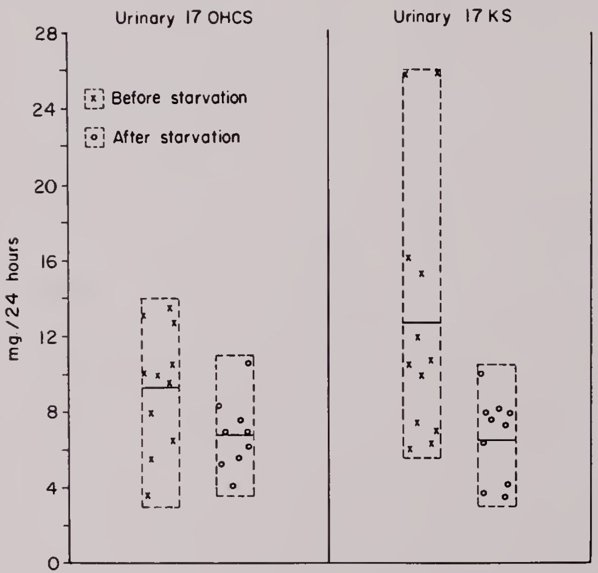

Fig. 2 — The effect of starvation on the 24-hour excretion of 17-hydroxycorticosteroids (17-OHCS) and 17-ketosteroids (17-KS) in the urine. Each x and each o represent a value for a single patient. The horizontal lines indicate the mean values.

vation, have been reported elsewhere[4] and are summarized in Figures 2 and 3. Urinary excretion of 17-hydroxycorticosteroids and 17-ketosteroids was decreased by 27 per cent and 47 per cent respectively. Plasma 17-hydroxycorticosteroids, measured as Porter-Silber chromogens, showed a marked increase during starvation, with a loss of the normal diurnal change. Response to ACTH was also increased. However, measurement of plasma cortisol by a more specific isotope dilution chromatographic technique did not show an increase in plasma cortisol, indicating that the increase in plasma Porter-Silber chromogens was due to nonadrenal steroidal material appearing in the plasma during starvation. The nature of this material was not determined in our studies.

All of the fasting patients showed mild to moderate acetonuria; however, five of the twelve had consistently negative plasma acetone. Quantitative ketone body measurements were not made. There was no significant change in plasma CO_2 content during starvation.

Serum uric acid rose markedly in the six women in whom serial measurements were made (Table 3). In some patients the peak serum uric acid level was reached by the sixth to eighth day of starvation, followed by a decrease in level (Figure 4). There were no clinical signs of gouty arthritis in any of the patients.

Blood urea nitrogen, serum cholesterol and blood sugar showed a moderate decrease during starvation, but the significance of these changes could not be tested because of the small numbers of observations made. In three patients, endogenous renal creatinine clearances were measured and each showed approximately a 50-per cent decrease from normal prestarvation values.

Measurements of hemoglobin, sedimentation rate, serum protein-bound iodine and thyroid I^{131} uptake showed no significant change with starvation. Electrocardiograms and electroencephalograms remained normal during starvation.

Discussion

Studies of obese subjects on adequate caloric intakes have shown that obesity is frequently associated with increased urinary 17-hydroxycorticosteroid excretion and increased cortisol production and disappearance rates.[8-15] The level of plasma 17-hydroxycorticosteroids has been reported to be low by some investigators[11,12] and normal by others.[10,13] Simkin[9] found the urinary excretion of 17-ketosteroids to be increased; however, others[8,10] have reported normal values in obesity. In our obese patients before starvation, mean values for evening and morning plasma 17-hydroxycorticosteroids and 24-hour urinary excretion of 17-hydroxycorticosteroids and 17-ketosteroids were within the accepted normal range. There was considerable variation within the group, with a few individuals having definitely elevated values. Elevated plasma 17-hydroxycorticosteroid levels were not necessarily associated with increased urinary excretion of 17-ketosteroids and 17-hydroxycorticosteroids. None of our subjects had low values for 8:00 AM plasma 17-hydroxycorticosteroids and the mean 8:00 AM level was considerably higher than our normal mean for lean subjects. Only one patient did not show a normal diurnal change in plasma 17-hydroxycorticosteroids. Response to adrenocorticotrophic hormones and SU-4885, and suppression with dexamethasone have been reported to be normal.[8,10,12,13]

Whether obese persons with laboratory evidence suggesting adrenal cortical hyperfunction have mild Cushing's disease has not been established. It has been concluded that obese subjects have a greater than normal conversion of secreted cortisol to urinary Porter-Silber chromogens.[12] Reduction in weight has resulted in return to normal of measurements of adrenal cortical function.[8,13,14,16] It has been demonstrated that urinary excretion rates for 17-hydroxycorticosteroids, and to a lesser degree 17-ketosteroids, are correlated with weight, height, and surface area.[17,18] Szenas and Pattee[11] have suggested that obesity is a continuous mechanical stress resulting in adrenal cortical hyperfunction. None of our obese patients had clinical findings of Cushing's disease either before or during starvation. It appears that in some patients obesity is associated with mild adrenal cortical hyper-

function; however, the increased adrenal cortical activity cannot be implicated as a cause of the obesity.

It has been demonstrated that short periods of total starvation are associated with few side effects, an absence of hunger and a consistent and progressive loss of weight.[1-3] Bloom[1] and Duncan and associates[2] reported an average daily weight loss of 2.5 to 3.0 lbs. Drenick et al.[3] observed patients during more prolonged fasts up to 117 days and reported a mean daily weight loss of less than 1 lb. Our patients lost an average of 2.1 lbs. per day during the first week but only 1.3 lbs. per day during the second week. This suggests that there is an initial excessive loss of body water, perhaps through both renal and insensible pathways, which decreases with continued fasting. We have also observed a rapid gain of 5-7 lbs. in weight during the first week post-starvation, not accounted for by caloric intake, which may represent retention of fluid and rehydration. None of our patients showed clinical signs of dehydration. With very prolonged periods of total starvation, orthostatic hypotension and marked losses of body protein and potassium have been reported.[3]

Starvation has been found to be almost invariably associated with a marked rise in serum uric acid.[1-3] This was also our observation. Drenick et al.[3] reported attacks of clinical gouty arthritis in two of their eleven patients. Murphy and Shipman[19] concluded that decreased urinary excretion of uric acid was related to a reduction in glomerular filtration rate during starvation, resulting in an alteration of renal tubular transport of uric acid. Cristofori and Duncan[20] have suggested that decreased levels of amino acids and carbohydrates in starving subjects result in diminished competition with uric acid for proximal renal tubular reabsorption, with a subsequent increase in serum uric acid. They found that Probenecid decreased serum uric acid and increased renal excretion of uric acid during starvation. Starvation of eight obese patients with a history of gouty arthritis, produced no acute attacks of gout despite increased serum uric acid levels. These investigators do not consider a history of gout to be a contraindication to periods of starvation up to 14 days.

Our observation of increased plasma Porter-Silber chromogens during starvation is at present not explained; however, it can be concluded that plasma cortisol is not significantly increased during starvation and that fasting for periods up to 14 days does not result in a stress stimulus to either the adrenal or pituitary glands.[7] The decreased urinary excretion of 17-hydroxycorticosteroids and 17-ketosteroids may be related to diminished renal excretory ability during starvation or decrease in pituitary or adrenal cortical activity.

It can be concluded that even the intractably obese person who does not lose weight on hypocaloric diets, will consistently lose 1-3 lbs. per day on total caloric deprivation. Total starvation for periods of 14-21 days appears to be safe and well tolerated, and there are no apparent, absolute contraindications. Although the obese patient had been restricted in physical activity during starvation, this is probably not necessary. Starvation of the ambulatory patient under close medical observation for short periods would seem to be safe and certainly economically more feasible than hospitalized fasts. The temptation to eat will, however, be greater and his control more difficult. It appears that even very limited food intake reduces the appetite suppression produced by total starvation.

The problem of the long-term management of obesity is not changed by intermittent periods of starvation. The obese patient must still alter his eating habits and attitudes toward food, if he is to continue to keep his weight within reasonable limits. The emotional and psychiatric aspects of obesity are not eliminated by starvation, and may in some cases be aggravated by total fasting. Periods of starvation in the management of obesity probably have their greatest value in demonstrating to the obese patient that he can lose weight, and in resolving the rationalization of many obese persons to the effect that diet and calories are not really involved in their weight problem.

Summary

Studies of adrenal cortical function in seventeen obese subjects on adequate caloric intakes indicated that their mean level of plasma 17-hydroxycorticosteroids was higher than that of normal lean persons. Adrenal cortical function was otherwise normal except for one patient who showed no diurnal change in plasma 17-hydroxycorticosteroids, and three who had moderate elevation of urinary 17-ketosteroid and/or 17-hydroxycorticosteroid excretion.

Total starvation of twelve obese women for a period of 13 days produced a consistent and progressive decrease in weight (mean loss: 1.8 lbs. per day). Serum uric acid and plasma Porter-Silber chromogens rose markedly, and excretion of 17-ketosteroids and 17-hydroxycorticosteroids decreased during starvation. Appetite was decreased and no serious clinical side effects were observed.

It is concluded that short periods of total starvation are a safe and effective way to initiate or supplement a broader program for the management of the obese patient.

ACHARD-THIERS SYNDROME

(Cushing's Syndrome)

This syndrome first was described in 1921 and is characterized by adenoma or hyperplasia of the adrenal cortex, diabetes mellitus and facial hirsutism in women with a masculine type of hypertrichosis of the face, voice changes, hypertrophy of the clitoris and occasionally a male psychogenic outlook. Obesity of the trunk, stria, acne, hypertension and occasionally osteoporosis may be present. Carbohydrate tolerance is decreased. The syndrome is thought to be the result of overproduction of the various adrenocortical hormones.

NUMEROUS SCREENING procedures for curable renovascular hypertension have been developed. The radioactive renogram,[1] the aortogram,[2] the "Howard test" and its various modifications,[3-5] and a variety of modifications of the intravenous pyelogram[6] are the more common examinations which have been employed. Split renal function studies have enjoyed the best results in predicting the curable disease states. They are, however, time-consuming, require special skills, and are not without morbidity and failure. The examination that the practicing physician resorts to for screening purposes because of its availability and ease of performance is the intravenous pyelogram. But numerous studies have demonstrated the inefficiency of the standard IVP in screening for curable renovascular hypertension.[6] Modifications of this procedure[6,7] have increased its efficiency; but there remains a group of undetectable lesions that represent 10 to 15 per cent of the curable cases.

Applying the basic principles of the renal physiologist, one of us introduced a modification of the intravenous pyelogram,[8] which has been employed in the evaluation of over 500 cases to date at some of the University Hospitals.[9] A review of the results of this examination in the first 407 patients, along with a number of concurrent renograms and aortograms, is the purpose of this paper.

Physiology

For the purpose of understanding what is visualized on the pyelogram the underlying physiological alterations can be oversimplified to two fundamental abnormalities. (1) There is a decrease in bloodflow to intact renal parenchyma, and (2), partially as a result of the first abnormality, hyperconcentration of certain substances excreted by the kidneys occurs. This is accomplished by the relative increase in absorption of sodium, and along with this water in the proximal tubules.

Detection of Curable Renovascular Hypertension

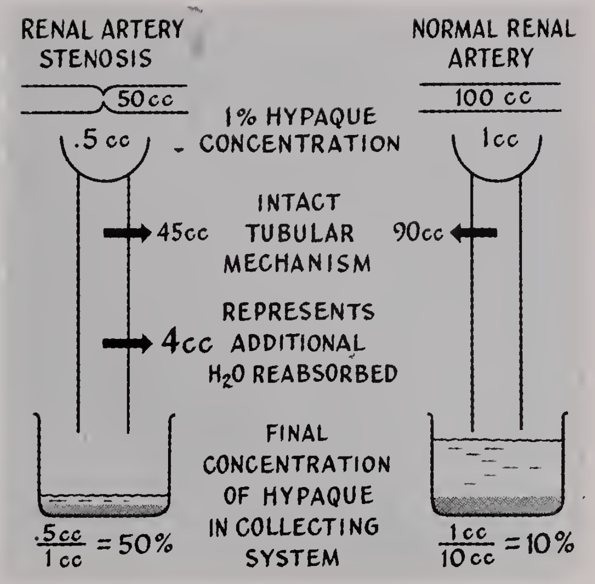

Fig. 1 — Schematic presentation of fundamental physiological abnormality in curable renovascular hypertension as it applies to intravenous pyelography.

The theories for the actual mechanisms by which these disturbances produce an increase in blood pressure are beyond the scope of this paper. Stamey has demonstrated that urea, when infused into the patient undergoing split renal function studies in the dehydrated state, will enhance the hyperconcentration of inulin, para-aminohippuric acid, and related substances.[4]

Hyperconcentration

Whether it be in the radioactive renogram, the routine or fast intravenous pyelogram, the Howard test, or aortography, the fundamental favorable prognostic sign known today is hyperconcentration. Figure 1 is an attempt at a more graphical representation of these physiological alterations. Through the stenotic renal vessel on the right side pass 50 c.c. of blood which is eventually filtered by the intact glomerulus. On the normal side during the same relative time, 100 c.c. have passed. The concentration crossing the glomeruli is equal and approximately one per cent when using 50 c.c. of sodium diatrizoate in an average individual. Also, the concentration of sodium diatrizoate is equal in the ultrafiltrate bilaterally.

Reabsorption

The intact tubular mechanism conserves sodium to the extent that 90 per cent of the water is reabsorbed from the urine on either side. Any substance which is not reabsorbed along with the sodium and water (such as sodium diatrizoate) will be further concentrated in the urine. As first described by Howard, in renal artery stenosis there is in addition an excess reabsorption of water in the tubules on the involved side. This is represented by the 4 c.c. For emphasis the water reabsorbed in the tubules on the abnormal side has been separated into 45 and 4 c.c. In practice, however, no such distinction can be made. In the containers at the bottom of the diagram the original 1 c.c. of hypaque is now 10 per cent of the final volume. On the involved side the original 0.5 c.c. now makes up 50 per cent of the final volume.

In summary, the decrease in glomerular filtration associated with renal artery stenosis is not accompanied by a decrease in tubular reabsorption. If tubular reabsorption were decreased to the same extent, then hyperconcentration would not occur. Since the tubular apparatus continues to reasorb sodium and water at a close to normal rate, hyperconcentration of nonreabsorbable substances (i.e. sodium diatrizoate) occurs.

The increased absorption of water has presumably resulted from the decreased flow of urine down the tubular system, a result of the decreased amount of blood presented to this kidney. Urea has been shown by Stamey to enhance this hyperconcentrating effect, presumably by presenting a large volume of fluid during a relatively short time.[4] In addition, urea is freely diffusable across the tubules, thus acting differently than Mannitol, which is not freely diffusable and perhaps less desirable.

Technique

Table 1 demonstrates the chronological approach to the performance of the urea flush test. The routine intravenous pyelogram preparation and scout film are obtained. No compression is used. Fifty c.c. of 75 per cent sodium diatrizoate are then injected rapidly and intravenously into a Y-tubing, which at one end has 500 c.c. of 8 per cent saline. The routine fast intravenous pyelogram films are taken at 30 seconds, 1, 2, 3, 5, and 10 minutes.

The three-minute film is developed and inspected. If equal concentration in both collecting systems has resulted, then the urea-saline mixture is allowed to run wide open. The 5 and 10-minute films serve as a baseline. Usually the 500 c.c. take from 8 to 10 minutes to infuse. During this infusion five films are obtained, exposed every three minutes.

Contraindications

Contraindications to this test include: (1) an elevated blood urea nitrogen, (2) moderate to severe congestive heart failure, (3) the usual contraindications to the injection of contrast agents.

Approximately 30 to 50 per cent of patients will complain of mild to moderate headache which is transient. Oral water hydration alleviates the majority of symptoms. No serious side effects have resulted.

Case Histories

The following two cases are included to demonstrate the typical findings in renovascular hypertension.

Case 1

A 37-year-old white male had a one-year history of severe hypertension and incapacitating symptoms. Headaches, blurred vision, dizziness, and signs and symptoms of aortic insufficiency were recorded. His blood pressure prior to surgery ranged from 200 to 220 systolic and 130 to 150 diastolic. Figure 2a shows hyperconcentration on the left side at 10 minutes; Figure 2b shows a holdup and positive flush test on the left side; Figure 2c shows the stenotic vessel with poststenotic dilatation. A pressure gradient of 40 mm. of Hq was measured across this vessel at the time of surgery and a bypass graft was performed. Within one week after surgery the blood pressure fell to 150/90. It has remained at this level for one year and the patient has been symptom-free.

Case 2

A 49-year-old white male, with a seven-week history of severe headaches, blurred vision, and dizziness, had preoperative blood pressures of 190 to 200/120 to 130. Figure 3a shows the delayed excretion of contrast in the collecting system on the right side; Figure 3b shows the density of contrast in the right

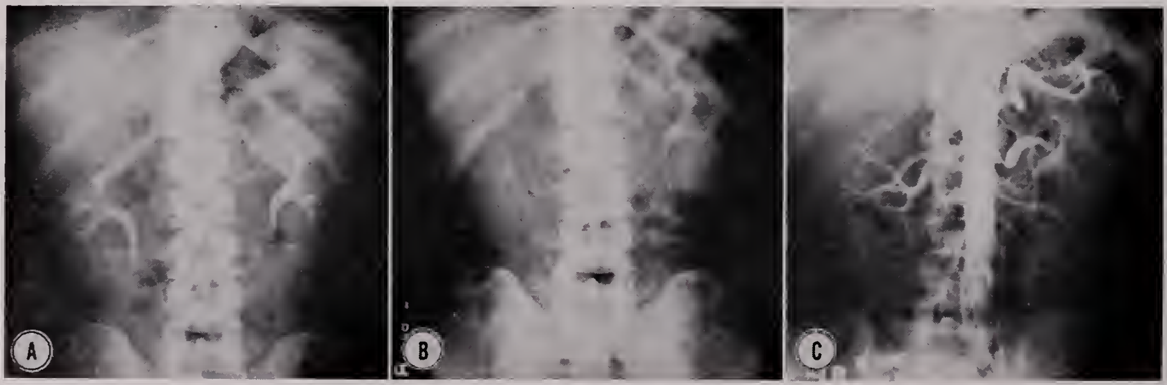

Fig. 2 (a) *Case 1.* Increased density of contrast agent in the left collecting system when compared to right. (b) Under influence of urea diuresis the normal right side washes out and there is a holdup of contrast on the left side. (c) Aortogram demonstrating left main renal artery stenosis with poststenotic dilatation.

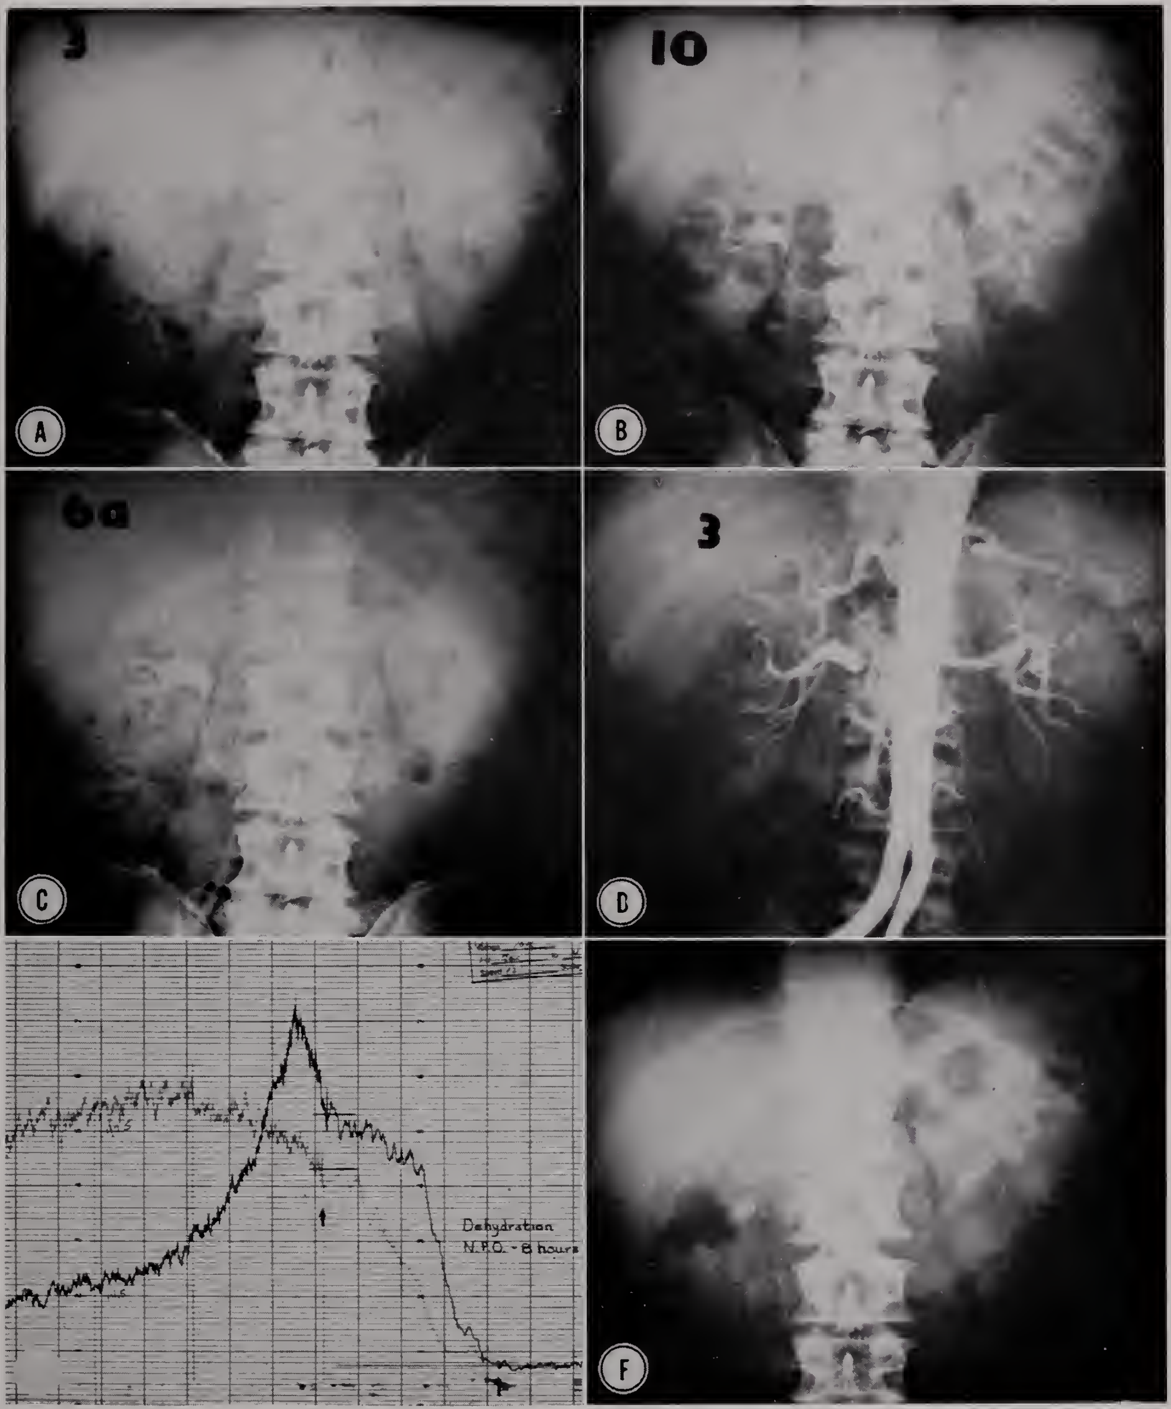

Fig. 3 (a) *Case 2.* Contrast has appeared in the left collecting system at three minutes. (b) At ten minutes there is increased concentration of the contrast agent in the right collecting system. (c) Washing out of contrast from the left collecting system while the right collecting system remains opacified. (d) Aortogram demonstrating right renal artery stenosis with poststenotic dilatation. (e) Renogram with characteristic changes of delayed vascular phase and peak with prolonged excretion on the involved side. (f) Postoperative washout which is equal and normal.

TABLE 1
Procedure — No Compression

1. Scout film.
2. Mix urea with saline (shake vigorously until all dissolved).
3. Start I.V. using Y-tubing with urea saline mixture.
4. Inject 50 c.c. of 75% hypaque as rapidly as possible (usually 20 to 40 seconds).
5. Allow urea to drip slowly to keep open.
6. Take films after hypaque injected at 1, 2, 3, 5, and 10 minutes; check for concentration in pelves (adequate concentration usually on 3-minute film, the 5 and 10-minute films serving as baseline for urea).
7. Allow urea to run wide open after film obtained with adequate concentration (usually 500 c.c. take 10 minutes).
8. Obtain X rays at 3, 6, 9, 12, and 15 minutes after urea starts (label A for After).
9. Check films to be sure study is complete.

to be greater than in the left on the eight-minute film; Figure 3c shows a positive washout test with holdup of contrast on the right; Figure 3d shows the renogram with the typical pattern for stenosis of the right renal artery; Figure 3e shows the aortogram with stenosis of the main renal artery and poststenotic dilatation; Figure 3f shows the postoperative urea flush test which has equal washout bilaterally.

The patient went to surgery and a vein graft was inserted over the area from which the atherosclerotic plaque was removed. His blood pressure fell immediately to 140/80. Two months later it was recorded as 146/90. He is now completely free of symptoms.

Results

Four hundred and seven unselected hypertensive patients were screened at the University of Minnesota, at the Veterans Administration Hospital in Minneapolis, and at Ancker Hospital in St. Paul over the past year. The examinations performed in these patients are seen in Table 2.

Ninety-six underwent retrograde or translumbar aortography, many of the group because of a high clinical suspicion or abnormal renogram. One hundred and twenty-five renograms were performed at the University.

In the 407, twelve positive cases (3 per cent) were obtained. The results of surgery in these cases are shown in Table 3. Seven patients were normotensive; four have shown significant improvement, and in one University case there was a return of blood pressure to the previous elevated levels two months after surgery. A follow-up aortogram revealed extensive infarction of the middle portion of the right kidney. Unfortunately, the patient refused further care. A similar situation, but with a much less extensive infarction, occurred with the Ancker patient. The important point to be gained from these two cases is that the etiology of the failure of cure in renovascular hypertension deserves considerable study.

Significant improvement was judged to be a drop of 20 degrees diastolic pressure to near normal levels along with complete amelioration of symptoms.

The results of the 96 aortograms are seen in Table 4. Eighteen patients were felt to have a significant lesion compatible with renovascular hypertension. Fourteen of this group underwent surgery; the other four either refused surgery or were deemed too great a surgical risk. Twelve of fourteen had positive flush tests; the results have been presented in Table 4. The other two patients had negative 'split renal' function studies and abnormal renograms; neither improved with surgical correction of the stenosis.

Renograms

Renograms were performed on 126 of these patients being evaluated for hypertension (Table 5). Seventy-six had a normal renogram and a normal urea washout test. Eight within a group of 76 also had aortograms performed, three of which were reported to show renal artery stenosis. One of these stenotic sites was felt to be hemodynamically significant. Only one patient of the entire group exhibited a normal renogram but an abnormal urea washout test and aortogram indicative of renal artery stenosis. This renogram was one of our early studies and was performed with the patient fully hydrated rather than partially dehydrated, as is presently done.

Renograms on 50 patients in this series were reported as abnormal. Twenty-two of these were quite typical for stenosis (delay in appearance and mild depression of peak function, and delay in excretion.) Of these, 17 have also had aortograms, all of which confirmed renal artery stenosis. The five remaining patients are presently being scheduled for follow-up aortography. The patterns from the 28 remaining patients were not typical of renal artery stenosis (rather isolated decreased function and/or delayed excretion,) and these patients had normal urea washout tests.

Summary and Conclusions

The urea flush test represents another application of radiological methods for the detection of abnormal physiological mechanisms. It may be premature to state the value of this test, but results today are encouraging. However, many questions remain unanswered. The role of the "normal" kidney which has been subject to high blood pressures for variable periods of time has not been clearly established. For this reason each patient who has undergone surgery for renovascular correction recently has had biopsies of both kidneys. Possibly this will give greater insight into the problem of curable renovascular hypertension.

The urea flush test presumably will suffer the same pitfalls as have the split renal function studies. With additional experience, it is feared that an occasional case of segmental arterial disease and symmetrical bilateral disease will be missed.

The urea flush test in our hands has proven

to be the most reliable prognosticator of curable renovascular hypertension. A larger experience will be necessary before any conclusion can be reached as to its reliability in screening for renovascular hypertension. Therefore, aortography should be performed in all patients in whom there is a marked clinical suspicion of this disease.

Of 407 flush tests 12 were positive. These all showed surgically correctable lesions as evaluated by angiography. Eleven of twelve cases were either cured or significantly improved. One had a surgical failure.

Acknowledgement

The authors extend appreciation to Dr. Donald H. Peterson, Chief of Radiology, Ancker Hospital, for allowing inclusion of data from Ancker Hospital studies.

WHAT'S YOUR DIAGNOSIS?

The patient was an eighteen-year-old, unmarried girl with onset of illness approximately three months prior to her admission to the hospital. She had lost approximately twenty-five pounds. There had been no nausea or vomiting though she had noted intermittent episodes of gassy eruptions and hyperacidity which was relieved with milk. Bowel function was normal. There had been no evidence of melena. The menstrual period had been delayed ten days and was associated with heavy flow and clots, but in the past two months the menstrual periods had been normal. She was admitted to a hospital, having felt faint and dizzy for three days. She felt no pain.

The physical examination revealed the patient to be pale. Blood pressure was 146/78, pulse 76. The abdomen was soft. Rectal examination was negative, and no mass or tenderness was elicited in the pelvis by digital examination.

Hemoglobin was found to be 6.9 grams, red cell count 2,130,000. Leukocytes and differentials were normal.

After five units of whole blood, the hemoglobin was found to be 14.5 grams, hematocrit 44 volume.

Fluid from the peritoneal cavity revealed an abundance of xanthochromic type fluid.

Numerous other laboratory and X-ray studies were made, all of which were reported to be negative. An operation was done and the diagnosis definitely established.

The Effectiveness of Erythromycin in Office Practice

JOHN T. PEWTERS, M.D.
SHERMAN B. CHILD, M.D.
JOHN A. HIATT, M.D.
Minneapolis, Minnesota

ERYTHROMYCIN IS a wide-spectrum antibiotic of proved effectiveness and unparalleled safety.[1-10] Side effects, including allergic manifestations, have been infrequent and relatively minor. The stearate and ethyl succinate salts have not been known to cause liver dysfunction, as seen with the propionyl ester lauryl sulfate.[11] It is the purpose of this study to examine the efficacy of erythromycin in the treatment of various infectious diseases encountered in an urban clinic devoted to the general practice of medicine and surgery.

Methods

Patients

A total of 159 patients were included in the study. Persons whose conditions were felt to specifically indicate a different antibiotic were excluded. Age distribution of the patients is shown in Table 1.

TABLE I
Age Distribution of Patients Under Study

Age in Years	No. of Patients
Less than 1	4

Diagnoses

Clinical diagnoses, 170 in all, are listed in Table 2. Generally, only the primary diagnosis was recorded when multiple diagnoses were made. However, all cases of acute bronchitis, tonsillitis, sinusitis, otitis media or pneumonia were recorded (these included 11 patients with concurrent diagnoses).

Treatment

Oral preparations (erythromycin stearate tablets and erythromycin ethyl succinate granules for oral suspension*) were administered for varying periods of therapy. Adults and older children received 1 gm. per day while smaller children received 20-30 mg./kg./day; medication was given in four divided doses daily.

---

*Supplied by Abbott Laboratories, North Chicago, Illinois, as Erythrocin Filmtab Tablets and Erythrocin Granules for Oral Suspension.

Results

Criteria for a satisfactory result in this study were: (1) complete clinical cure within the period of antibiotic therapy, (2) no subsequent recurrence attributable to the original infection, and (3) no complaint of side effects. According to these criteria, satisfactory results were obtained in 127 patients (see Table 2).

An analysis of the 32 patients recorded as failures revealed that 19 were so classified because they failed to show an adequate clinical response. Sixteen of these were promptly cured with other antibiotics; diagnoses in the other three patients were tonsillitis (probably of viral etiology), acne vulgaris and bronchiectasis. Three patients were recorded as failures because recurrences were reported. The other 10 treatment failures were so classified because of reported side effects including upset stomach, indigestion, and one case each of dizziness and diarrhea. Seven of the 10 patients stopped medication without consulting with their physicians. The complaints of six persons, including those reporting diarrhea and dizziness, were questionable; for example, one of the patients reporting "side effects" was suffering from fever and malaise due to infectious mononucleosis and, in addition, was taking large quantities of aspirin and a cold preparation containing codeine.

Throat cultures, obtained from 22 patients with respiratory infections, and a skin culture from another patient were streaked on-

to sheep's blood-agar plates. Of these, three yielded beta hemolytic streptococci (all patients responded to treatment); nine yielded Staphylococcus aureus (five patients responded to treatment); four, including the skin culture, grew gram-negative rods (none of the patients responded); and only nonpathogens were found in seven cultures (four patients responded to treatment).

Discussion

Of 32 patients classified as treatment failures, there were nine in whom this classification was questionable. Three of these patients, recorded as failures because of inadequate clinical response, were not cured with other antibiotics; the "side effects" of six patients were considered likely to be due to factors other than the medication under study. Thus, excluding the nine questionable failures, only 16 patients (10%) failed to respond to treatment because the medication lacked adequate antibacterial activity, three (1.9 %) responded well to treatment but had recurrences, and four (2.5%) exhibited side effects definitely attributed to the medication.

Acute bronchitis was diagnosed in one third of the patients and, in these patients, therapeutic response seemed least favorable. Treatment failures were recorded in 14 (26%) of the bronchitis patients, all of whom were cured following a change to another antibiotic.

Erythromycin was surprisingly effective in patients with tonsillitis, since penicillin is generally considered to be the treatment of choice for this condition. Of the 25 patients with tonsillitis, five were classified as treatment failures. However, two of these cases were so recorded due to gastrointestinal side effects, and another was considered to be of viral etiology. The other two cases were recurrences; one was cured following an additional course of erythromycin therapy and the other occurred in a patient whose tonsils were so badly diseased as to require tonsillectomy.

Summary and Conclusions

Erythromycin stearate and ethyl succinate were used to treat 159 outpatients having a total of 170 clinical diagnoses. Clinical cures were effected in most patients. Analysis of the treatment failures indicated that the antibiotic is less effective against acute bronchitis than the other "office" infections treated.

It is concluded that erythromycin is effective against most infections encountered in routine office practice. Side effects with the preparations used were shown to be relatively infrequent.

ACUTE VASCULAR injuries may be divided into two categories: first, those producing actual injury to the artery or veins, and second, those in which no actual direct injury to the vessel itself occurs, but the symptoms presenting are those of vascular insufficiency.

Injuries to the artery may be in the nature of contusion with thrombosis, actual laceration, or complete separation of the vessels. Various mechanisms producing these types of lesions are illustrated in Figure 1. Of these three, the most important clinically is contusion. This injury may result from blunt trauma without any obvious trauma to skin (Figure 1c); it may also occur in bumper injuries. Injury to the bone may be absent and the arterial injury overlooked. Arterial spasm is the most common diagnosis under the circumstances. Determination of circulation distal to the point of blunt trauma by palpation of pulses, oscillometric readings, and arteriography, if necessary, are very essential (Figure 2). The absence of external bleeding, swelling, and hematoma formation may make the diagnosis obscure. Exploration of the artery should be done if no improvement in circulation is noted after appropriate sympathetic nerve blocks.

Recognition of Arterial Injury

The important signs of the interruption of a major artery in an extremity are pallor, loss of peripheral pulses, rapidly developing anesthesia of the skin in the distal portion and loss of function of the small muscles of the hand or foot. Reflex arterial spasm also causes pallor and loss of pulses but rarely, if ever, complete anesthesia or small muscle paralysis. The effect of reflex vasoconstriction diminishes with relief of the pain by drugs and protection from motion of the fracture site. The interpretation of the finding of neurologic deficits, such as anesthesia and paralysis, will become more difficult when nerve injury is also present. Loss of sensation and motor function secondary to specific nerve interruption will have a definite and predictable pattern, whereas that associated with terminal ischemia of the part will involve it in a more general way without regard to a specific nerve distribution.

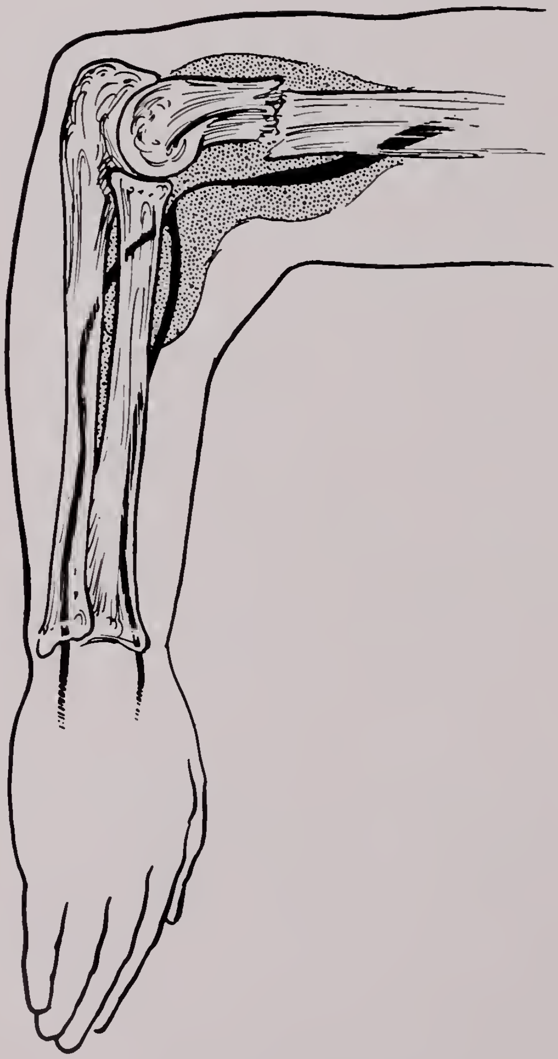

Fig. 4 — Hematoma formation following supracondylar fracture of humerus. Brachial artery is compressed as well as being in spasm.

Surgical Treatment

Surgical treatment of contusion always involves resection of the contused area, since evacuation of the clot alone will result in failure. This same principle applies to lacerated arteries where the destruction is too great for primary suture. Primary anastomosis or interposing of a saphenous vein autograft is the procedure of choice (Figure 3). When the artery is lacerated a hematoma may form, or if the artery is completely divided it may retract without too much bleeding. Where it is partially lacerated and a hematoma forms, a pulsating mass may result and present as a false aneurysm or pulsating hematoma. The history of injury and the presence of pulsating mass with a systolic bruit heard over it makes the diagnosis. In these cases resection of the involved segment is usually necessary with reconstruction of the artery by anastomosis or graft. Where both artery and vein are injured, a pulsating mass may appear with a palpable thrill. A continuous murmur is heard over the mass immediately or within hours to a few days. The presence of a continuous thrill and continuous murmur makes the diagnosis of an arteriovenous fistula. Although an arteriogram will confirm the presence of a false aneurysm or arteriovenous fistula, physical examination alone will result in a proper diagnosis in every case. The repair of this condition involves dissection of the fistula with either repair of the vein primarily or ligation of the vein, always with restoration of the continuity of the artery.

Most of the injuries to arteries associated with fractures occur when the fracture is adjacent to a point such as in a supracondylar fracture of the humerus or femur. Many of these are compound fractures, and inspection of the vessels is extremely important at the time of the primary care of the wound. Where the wound is not compound, careful palpation of distal pulses after reduction of the fracture is extremely important, as a large hematoma may result in gradual compression of the artery (Figure 4). With evidence of arterial obstruction, the brachial artery should be explored and appropriate repair done. At times, if there is extensive contusion of the entire forearm, distal thrombosis of the small vessels may prohibit successful restoration of vascular continuity. When injuries of the arteries are associated with fractures of the long bone, such as the femur, it is important that careful attention be paid to fixation of the fracture at the time of vascular repair. If traction alone is used, it is very important that the traction not be disrupted, since the vascular graft that may have been done will be endangered. Massive hematoma in the thigh from a fractured femur may indicate possible blood vessel injury. Arteriograms will help define the situation.

Complications

Ischemic Contracture

An entity that has been described for many years is that of Volkmann's ischemic con-

PLATE 4

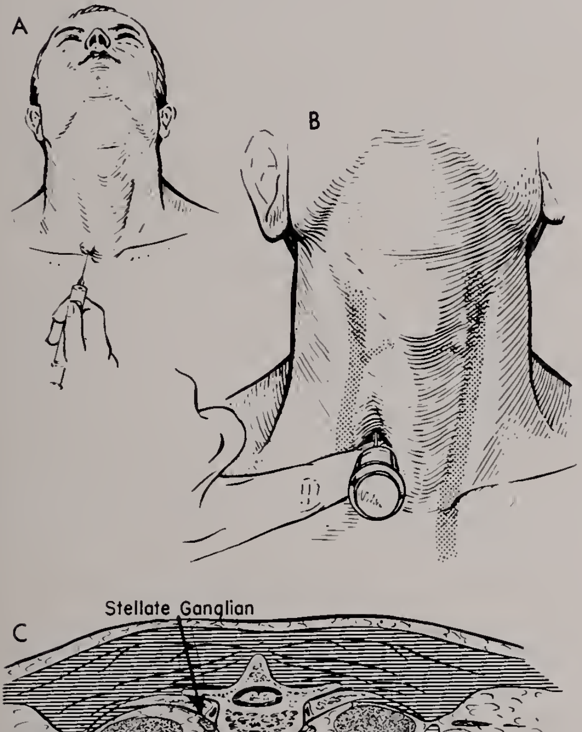

Fig. 5 — Stellate Ganglion Blocks: A and B. A 10 cc. syringe with a 2-inch gauge needle attached is filled with 2% procaine hydrochloride. The finger is used to pull the carotid vessels laterally and the needle is directed posteriorly towards the 7th cervical vertebra. C. After hitting the fascial covering of the cervical spine, the needle is withdrawn slightly and the anesthetic agent is injected.

PLATE 3

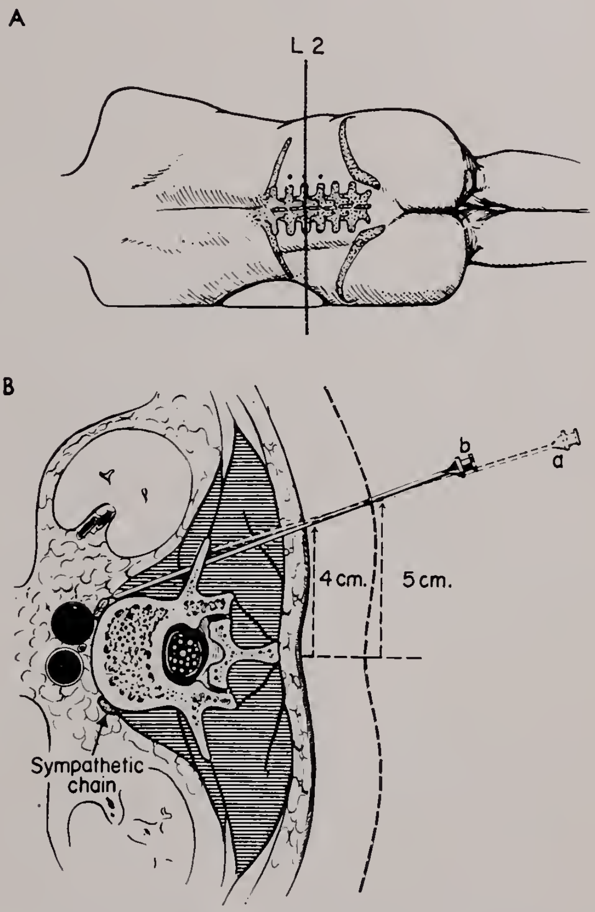

Fig. 6 — Lumbar Sympathetic Ganglion Block: A. The patient may be placed either laterally as shown, or in the prone position. Needles 7 inches long are used for the injection. B. The needle is inserted until it hits the side of the lumbar vertebra and then advanced to the anterior aspect. Injection is made in the appropriate place. The inferior vena cava on the right and the aorta on the left may be entered inadvertently. The needle is then withdrawn and injection made.

tracture. It has been chiefly noted following supracondylar fractures of the humerus or both bones of the forearm and supposedly is brought on by continued swelling after immobilization of a point in flexion. It is either related to actual damage to the artery at the time of the fracture or may be related to continued swelling inside of a case, with first venous occlusion followed by subsequent arterial occlusion with swelling and resultant obstruction of arterial supply and ischemia. The end result is the production of an atrophied forearm and useless hand. This condition in reality reflects improper management of vascular injury secondary to trauma and is preventable. Careful observation of an extremity placed in a case is important in determining any undue swelling and loss of pulses. Prompt removal of the cast may relieve the situation. Exploration with fasciotomy in an extremely swollen extremity may drain the hematoma with restoration of pulse. If the artery is in severe spasm, local application of papaverine may help; in other cases forcible distention of the artery with saline solution will result in a patent vessel. If there is any indication of contusion, then the artery must be resected and treated as outlined previously.

Post-traumatic Sympathetic Dystrophy

A final group of patients are those in whom the trauma may result in a fracture or be very minor in nature. In these patients there is no actual injury to the artery itself. The resultant series of events are those of continuing reflex vasospasm with subsequent demineralization of bone, the syndrome being known as causalgia or post-traumatic sympathetic dystrophy. As this condition is often overlooked or treated as a form of psychoneurosis, it is very important in industrial medicine. This syndrome may follow a very minor trauma to a hand, for example, or may be associated with other orthopedic conditions such as fractures of the ankle or metatarsal bones. The pain is severe and chronic in nature, aggravated at times by changes in temperature; the extremity appears cold with increased sweating. As the symptoms may be aggravated by emotional upsets, these patients are sometimes labelled malingerers. The diagnosis is made by appropriate sympathetic nerve blocks. In the upper extremity a stellate ganglion block is done with the anterior approach (Figure 5). The area is infiltrated, resulting in most cases in an adequate sympathetic nerve block. In the lower extremity a lumbar sympathetic block is done as illustrated in Figure 6. If the blocks produce relief of pain, then the diagnosis is most often that of post-traumatic sympathetic dystrophy. In some cases two or three nerve blocks may actually produce permanent relief of pain. If, however, after two to three blocks the relief of pain is still only temporary, then a sympathectomy will provide a permanent cure.

The Penalty of Overweight

Obesity can cause dyspnoea, excessive fatigue, and limited capacity for performing muscular work by increasing the body load. In all types of work, mechanical efficiency is impaired by obesity.

Renovascular Hypertension*

Clinical Detection

ROLF ANDREASSEN, M.D.
Minneapolis, Minnesota

THE DETECTION of renovascular hypertension depends first, on clues found in the clinical history and physical examination; second, on clues derived from the clinical laboratory and ordinary X-ray examinations, and finally on aortography and renal arteriography. During such an investigation, tests should be made to define if possible a specific etiology for the hypertension, whether it be renal or otherwise. Before launching such an investigation one should first be satisfied that significant hypertension is present by means of repeated blood-pressure determinations and a search for signs of high-blood-pressure effect on the heart, eyes, and kidneys.

It should be noted first of all that renovascular hypertension cannot be distinguished from essential hypertension by its severity, by its variability, by its response to rest in the hospital, or by its response to medicines, since renal hypertension may be mild or severe, may vary greatly from time to time, may decline markedly during hospital repose, and may respond well to medicines, just as does essential hypertension.[1]

History

The family history will often yield a history of hypertension among the relatives; a lower incidence may be expected in other types of hypertension. If a family history of hypertension is absent, this should make one more willing to pursue the investigation to the last degree.

Duration

The history of abrupt or recent onset of hypertension is often found in renovascular hypertension, whereas this is not so with essential hypertension.[1]

The duration of the hypertension is also of prognostic importance, since the chances of improvement with surgical relief are smaller if the hypertension has been present for more than five years.[2] However, we have seen cure result from nephrectomy performed as long as ten years after severe injury to one kidney.

Injury or Infection

A history of injury to the kidney in the past can be an important clue in some cases of renovascular hypertension. Chronic pyelonephritis is likewise a common cause of renal hypertension.[3]

---

*Read before the Minnesota Radiological Society Meeting, February 29, 1964, Minneapolis, Minnesota.

If malignant hypertension is found without a prior history of a lesser degree of hypertension for a number of years, one should suspect renovascular hypertension, since malignant essential hypertension is almost always superimposed upon an essential hypertension of lesser severity of several years duration.[1]

Pain in the flank can be an important clue to the possibility of segmental renal artery occlusion, particularly in patients with a cardiac source for emboli.[1]

Age

The age of the patient is important to consider, because essential hypertension usually begins in the middle years, with the average onset in the thirties. If it begins in youth, it is not usually essential hypertension; nor is it such when the onset is in old age.[1] Both old and young patients should therefore receive careful study.

Symptom Complex

Paroxysmal headache, sweating, and pounding of the heart can be an important clue to the presence of pheochromocytoma, particularly in cases with paroxysmal elevation in the blood pressure. In patients with sustained hypertension, the absence of weight loss is strong evidence against pheochromocytoma, since weight loss associated with hypermetabolism is almost universal when pheochromocytoma produces sustained hypertension.[4] Muscle weakness and cramps, polyuria, polydipsia, paresthesias, and tetany would strongly suggest primary aldosteronism as the cause of the hypertension.[5]

Physical Examination

The Blood Pressure

The blood pressure should be measured in the leg of every patient with hypertension in the arms. It is not sufficient to palpate the femoral pulse, for coarctation with complete or nearly complete closure of the aorta with normal femoral pulses and blood pressures can be observed. If the blood pressure in the legs is not higher than that in the arms, then further search for coarctation should be made.

A severe degree of hypertensive retinopathy, with hemorrhages and exudates, may be found either in essential hypertension or renal hypertension. Its presence, however, would be strongly against the diagnosis of primary aldosteronism, since such a degree of retinopathy is rare in that disease.[5]

Carpopedal Spasm

Carpopedal spasm with a Trousseau sign upon the application of the blood pressure cuff can be an important sign indicating primary aldosteronism. This is attributable to the alkalosis which results from the excessive loss of potassium in this disease.

Bruit

A bruit over the renal arteries, usually best heard in the upper lateral abdomen, is found in some cases of renovascular hypertension, but unfortunately in a relatively small percentage.[1]

Clinical Laboratory Tests

Serum potassium and CO_2 should be determined in any hypertensive patient where primary aldosteronism is a possibility, searching for the hypokalemia and alkalosis which occurs in this disease. The finding of a persistently dilute and alkaline urine may also be a clue to the presence of aldosteronism. Even if the serum levels of potassium are not depressed to a diagnostic degree, the diagnosis may be secured by the determination of the ratio of sodium to potassium in the saliva when the patient is on a controlled diet, since aldosterone depresses the secretion of sodium in the saliva.[5]

An elevation of the blood glucose and elevation of the basal metabolic rate may be important indicators of pheochromocytoma.[6]

A much neglected simple laboratory test in hypertension is the search for cellular casts in the urine. Finding that the kidney sheds such casts is of prime importance, since this occurs only in nephritis, white cell casts predominating in pyelonephritis, and red cell casts in glomerulonephritis. Indeed, such casts may be regarded as pathognomonic of these diseases.[3]

Tests for Pheochromocytoma

In any patient where pheochromocytoma remains a possibility, either a regitine or a histamine test should be done, depending on the level of blood pressure at the time of the testing. If the blood pressure is 170/110 or above, the regitine test is sensitive and reliable if done properly. Proper conduct of the test means that antihypertensive drugs should be withdrawn for a period of two weeks, since false negative tests will otherwise be frequent. Sedatives should also be withdrawn for a period of 48 hours, since false positives will otherwise be frequent.[6] If the blood pressure at the time of the testing is below 170/110, then a provocative test with histamine should be performed, injecting 0.05 mg. intravenously, observing the blood pressure every twenty to thirty seconds thereafter. A syringe full of regitine should be attached to the needle after the histamine is injected in case it is needed to control a hypertensive reaction.

Where such testing is not definitive, the urine catecholamines, or the derivative, vanylmandelic acid, may be determined. Single normal values do not, however, rule out pheochromocytoma.[6]

Intravenous Pyelogram and Radioactive Renogram

If pheochromocytoma, primary aldosteronism, coarctation, and glomerulonephritis have not been discovered as possible causes of the hypertension, then all patients should have an intravenous pyelogram, or a radioactive renogram if this is available. The pyelogram may reveal pathology such as polycystic disease, pyelonephritis, or congenital hypoplasia to explain the hypertension. The sensitivity of the pyelogram in renovascular disease may be increased by obtaining early films without compression. It is important to look for a disparity in the time of appearance of the dye in the two kidneys, and also for any disparity in the length of the two kidneys. Either may be a sign of renovascular disease. However, normal findings do not rule out renovascular hypertension.[1,2,7,8] The sensitivity of the procedure may be increased further by comparing the speed of washout of the dye from the two kidneys after a diuresis from water or urea.[9,10]

If such a disparity is found on the intravenous pyelogram or the radioactive renogram, then aortography is obviously indicated. Even if the pyelogram and renogram are negative, aortography should nevertheless be performed in the following patients: the young patient, the old patient, the patient with recent onset of hypertension or abrupt onset or acceleration of hypertension, the patient with a bruit over the renal artery or with a history of injury to the kidneys, the patient without a family history of hypertension, and in all patients who have malignant hypertension.

Using all of these criteria for selection of patients for aortography, very few patients with renovascular hypertension will be missed.[1] If renovascular stenosis is found, but the significance of the arterial lesion is in doubt, measurements of pressures distal to the lesion,[10] or differential function studies of the two kidneys, may help settle the question of whether the lesion is producing the hypertension.[11] Since differential function studies are indirect indicators of whether the kidney is producing pressor agents, no perfect correlation is to be expected. A reliable method for measurement of renal pressor agents from the individual human kidney would be the definitive measure of the pathologic physiology.[12]

Blood Alcohol from Corpse Admissible*

Intoxication tests on blood obtained from a corpse were held admissible in a passenger's suit against a bus company. The injuries to the passenger were sustained when the bus collided with an automobile. Evidence that the driver of the automobile was intoxicated was admissible even though the intoxication test was made of blood obtained from the body of the deceased driver. Evidence of the blood test was given by a pathologist, whose duty it was to investigate deaths for the county coroner. He testified that he drew blood out of the driver's heart after he had expired. A test of the blood showed .35 grams of alcohol per 100 millimeters of blood, indicating intoxication.

The supreme court of Missouri refused to rule on the passenger's contention that obtaining the blood from a corpse amounted to an unconstitutional search and seizure. The bus passenger contended that evidence of the blood test should not have been admitted because it was obtained by unlawful and criminal desecration of a dead body, repugnant to common ideas of decency, amounting to unconstitutional search and seizure. The court said that the bus passenger had no standing to raise the question since the constitutional right to freedom from unlawful search and seizure is a personal one, and there was no relationship between the automobile driver and the bus passenger.

Diener v. Mid-American Coaches, Inc. 378 S. W. 2d 509 (Mo., Apr. 13, 1964)

Editor's Note: Alcohol levels for determining intoxication can be made on the breath, the urine, and the blood, and can be interpreted in relation to the blood alcohol value. The urine value is 1.3 times that of the venous blood, and the breath (alveolar air) has a ratio of 2100 to 1. From these figures, the equivalent amount of alcohol in the blood can be calculated. In order that a 150 lb. man reach a blood alcohol level of .15, it would be necessary for him to drink approximately 6 ounces of 100 proof liquor. One bottle of beer (8 oz.-6%), one glass of wine (4 oz-20%), and one ounce of whiskey (100 proof-50%) provide approximately equal quantities of alcohol.*

April Saints and Medicine

Familiar as an April saint is Bernadette (1844-1879), identified with the shrine at Lourdes, France, the healing powers of whose grotto waters were revealed to her as a young girl by the Virgin Mary. This shrine became world-famous and continues to this day to be a Mecca for the ailing who believe in the curative properties of its waters and are sometimes mysteriously and inexplicably benefited thereby.

St. Bernadette's commemorative day is April 16.

Drinking a little too much is drinking a great deal too much. — German proverb

The word impossible is not in my dictionary. — Napoleon

The Surgeon's Role in Renovascular Hypertension*

FRANK E. JOHNSON, M.D.
Minneapolis, Minnesota

RENOVASCULAR HYPERTENSION has its basis in a mechanical derangement and thus falls into the category of problems with which the surgeon deals most effectively. Our present understanding of this problem is based on the astute observations of Bright[1] at the autopsy table, the brilliant laboratory study of Goldblatt,[3] and the clinical application of knowledge accumulated to 1954 by Freeman,[2] who diagnosed renal artery obstruction by aortography and cured his patient's hypertension with thromboendarterectomy. An indication of the rapid development in this field is the fact that Poutasse[6] wrote in 1956 that the proper treatment for a patient with hypertension due to renal ischemia is nephrectomy. Yet this same author was responsible for stimulating interest in corrective surgery for renovascular hypertension by his report in 1959 of a series of cases successfully treated by arterial reconstruction.[7]

The surgeon leans heavily upon the angiogram in planning and executing renovascular reconstructive procedures, much as he depends on accurate mapping of each of the segmental bronchi of both lungs in planning the surgical treatment for bronchiectasis. He is now often content to have an adequate film of the main renal arteries but will in the future be asking for ever more perfection in demonstrating the entire renal arterial tree on both sides. It is possible to restore arterial flow through reconstructive procedures to vessels the size of the anterior or posterior tibial artery in the leg. Thus it does not seem unreasonable for us to expect to be able to reconstruct individual renal segmental arteries.

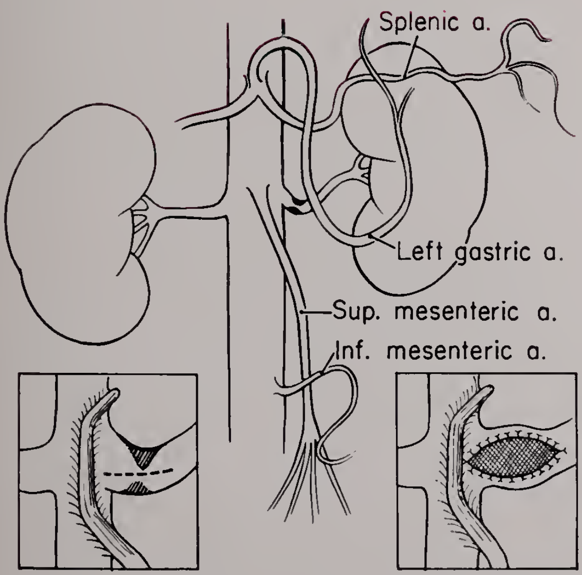

Fig. 1 — Diagram of method of renal artery reconstruction employed in our first patient, who was operated upon in July, 1960, at age 39. His malignant hypertension was corrected and he remains normotensive to this time.

---

*Read before the Minnesota Radiological Society Meeting, February 29, 1964, Minneapolis, Minnesota.

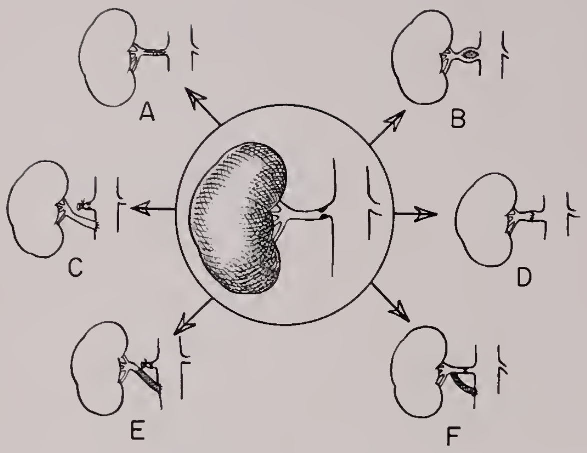

Fig. 2 — Diagram of some of the methods available for reconstruction of the renal artery. a. Endarterectomy. b. Patch graft. Vascular prosthetic material or autogenous vein may be used as the patch. The latter is preferred. c. Reimplantation of renal artery to side of aorta. d. Excision of obstructed segment and end-to-end anastomosis. e. Vascular prosthetic or autogenous vein graft from aorta with end-to-end anastomosis. f. Graft (prosthetic or autogenous vein) from aorta to side of renal artery.

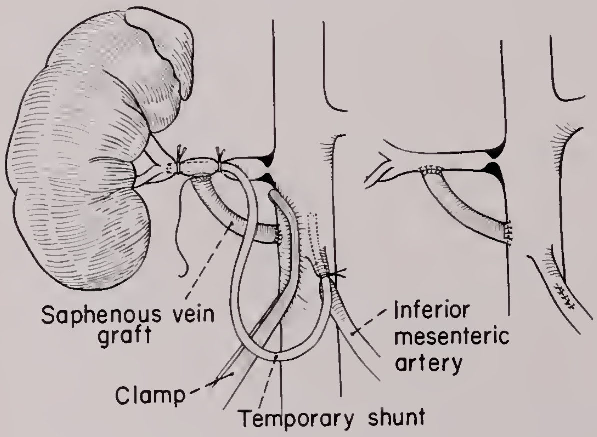

Fig. 3 — Diagram of method using a temporary external shunt to maintain blood supply to the kidney during the period necessary to construct the permanent bypass. This eliminates the need for hurry and permits the fine techniques applicable to autogenous vein grafts and mandatory in reconstruction of small arteries.

Available Surgical Techniques

Corrective surgery implies that the basic mechanical problem be remedied with preservation of all possible functioning parenchyma. Nephrectomy cannot be considered a corrective procedure for this disorder, even though it could relieve the hypertension. Some of the techniques available to the surgeon are illustrated in Figures 1, 2 and 3. The aim at operation is to restore a pulsatile flow at aortic pressure to the renal arterial system.

The incision is mid-line from the xiphoid to the pubis. Complete exploration of the abdominal cavity is carried out with palpation of the adrenal glands, at the least. A needle biopsy is taken from each kidney so that the extent of parenchymal disturbance can be used as a guide in the future management of the patient. The pressure is measured in the aorta and in the renal artery distal to the obstruction. It is arbitrarily stated that those patients who have 40 mm. of mercury less pressure in the renal artery than in the aorta will have good results from arterial reconstruction. Those who have no gradient have nothing to gain from arterial reconstruction and should therefore not be subjected to the risks of this procedure.

Having assessed the local pathology, and having correlated this with the preoperative angiogram, the plan of arterial reconstruction is made. The choice of procedure will depend on the individual mechanical problem to be dealt with and the surgeon's preference based on his experience with the methods available.

Instituting Diuresis

At this point an intravenous drip of 25 to 50 grams of Mannitol in a 10 or 20 per cent solution is started, because there is evidence that this osmotic diuretic is of value in assisting the kidney to recover from ischemia.[5] The patient is given 1.5 to 2.0 mg. per kilo of heparin intravenously to avoid clotting during the time of reconstruction.

Interrupting Blood Supply to Kidney

The actual reconstructive procedure is planned so that the kidney will be without blood supply for as short a time as possible. It apparently is the practice of the majority of surgeons to interrupt renal arterial flow completely during the period of reconstruction. All will make this period as short as possible, but Poutasse and others will accept thirty minutes of total ischemia without concern. There is no doubt, however, that the time factor does put emphasis on speed. Total body hypothermia may be employed to extend the tolerable ischemia time, but this method has some inherent problems which limit its usefulness. It would, of course, be ideal if the ischemia time were zero. To this end we have used temporary external and internal shunts (Fig. 3), which have proved eminently satisfactory in our reconstruction of the extracranial cerebral arteries where, if the tolerable ischemia time is exceeded, the effect is so distressing and immediately apparent.

Hyperbaric Oxygenation

Hyperbaric oxygenation will extend the tolerable ischemia time also, and it undoubtedly will find application in renovascular surgery for the solitary kidney and those cases with bilateral renal artery stenosis with renal failure.

Partial Nephrectomy

Partial nephrectomy may be effective in reducing the hypertension when a segmental artery unsuitable for reconstruction is involved. In those cases where arterial reconstruction is not possible, or has failed for some reason, nephrectomy may still be employed in treatment of the hypertension. It should not, however, be chosen as the initial procedure any more than amputation of an extremity for a gangrenous digit should now be undertaken without obtaining angiograms and considering the possibility of arterial reconstruction.

End Results

The number of cases in our personal series and the duration of follow-up does not permit valid statistical analysis. Morris et al.,[4] 1963, had a series of two hundred cases with follow-up from three months to five years. Their patients ranged in age from eight to seventy-two years. Sixty-five per cent were males. Hypertension was present for less than five years in sixty-five per cent. Arteriosclerosis accounted for the obstruction in eight-five per cent and fibromuscular hyperplasia in thirteen per cent. The stenosis involved the proximal third of the renal artery in seventy-five per cent. Renovascular reconstruction resulted in the blood pressure returning to normal in eighty per cent and decreasing significantly in another eight per cent. Such results speak well for Morris' careful selection of patients as well as a skillfully executed reconstruction.

Of great interest is the fact that twelve of these patients were operated upon for renal failure. Carefully done aortograms had revealed bilateral renal artery stenosis. In this seriously-ill, high-risk group, arterial reconstruction was undertaken with only one surgical death. The remaining eleven patients were reported to have improved renal function, and the hypertension was said to be controlled in the majority.

Summary

Dependence upon the accuracy of the preoperative angiogram and our growing experience with improved surgical technique will demand increasing perfection in angiographic mapping.

It would seem from the report of Morris that we must now consider for renal angiography and possible arterial reconstruction certain selected patients with chronic renal failure.

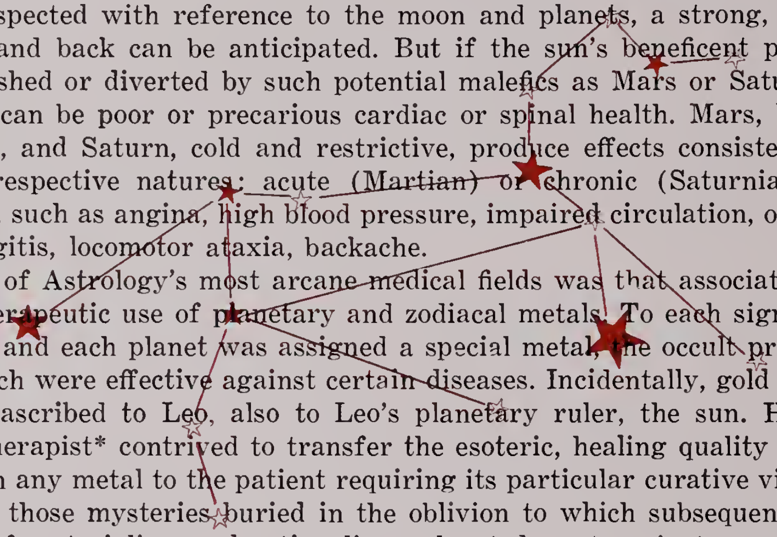
Astrology and Medicine — Leo, the Lion

The constellation of Leo, the Lion, is familiar to many an amateur stargazer in the northern hemisphere for its royal prominence in the zodiac during the spring months. Since the sun occupies this sign from about July 22 to August 22, any individual born between these dates is a Leo native.

Astrologically Leo governs the heart and circulatory system, also the spinal cord and column. If, at the time of a native's birth, the sun is favorably aspected with reference to the moon and planets, a strong, healthy heart and back can be anticipated. But if the sun's beneficent power is diminished or diverted by such potential malefics as Mars or Saturn, the result can be poor or precarious cardiac or spinal health. Mars, hot and violent, and Saturn, cold and restrictive, produce effects consistent with their respective natures: acute (Martian) or chronic (Saturnian) disorders, such as angina, high blood pressure, impaired circulation, or spinal meningitis, locomotor ataxia, backache.

One of Astrology's most arcane medical fields was that associated with the therapeutic use of planetary and zodiacal metals. To each sign of the zodiac and each planet was assigned a special metal, the occult properties of which were effective against certain diseases. Incidentally, gold was the metal ascribed to Leo, also to Leo's planetary ruler, the sun. How the astrotherapist* contrived to transfer the esoteric, healing quality crystallized in any metal to the patient requiring its particular curative virtues is one of those mysteries buried in the oblivion to which subsequent incursions of materialism and rationalism relegated most ancient, secret practices.



High in the southern sky at mid evening in April Leo is fully visible in its regal splendor, proceeding westward. The six bright stars delineating the forepart of the Lion are known as the Sickel, the brilliant 1.3 magnitude star, Regulus, marking the end of the handle.

From the astrological identification of Leo with the heart derive the adjective 'lion-hearted'; the appellation 'Coeur de Lion'; and the name 'Leonard.'

The Value of Arteriography in the Assessment of Renovascular Hypertension[*]

KURT AMPLATZ, M.D.[**]
STEPHEN A. KIEFFER, M.D.[†]
Minneapolis, Minnesota

RENAL ARTERIOGRAPHY is one of the most important diagnostic procedures in the work-up of patients with suspected renovascular hypertension. With the newer transfemoral catheterization techniques, the procedure carries a negligible risk. The main value of renal arteriography lies in the exclusion or anatomic demonstration of lesions which may cause renovascular hypertension. However, it must be emphasized that the demonstration of such a lesion does not establish it as the cause of the patient's hypertension; in all cases, the angiographic findings must be correlated with other clinical data.

Indications

It is our feeling that renal arteriography is indicated in all patients with suspected renovascular hypertension on the basis of clinical history, intravenous urogram, and isotope renogram. Delineation of the renovascular tree not only establishes the presence of a localized correctible lesion; it also aids the surgeon in planning a corrective procedure and allows evaluation of the contralateral renovascular tree, which is occasionally involved by the same process but whose abnormal physiology may be masked by the more predominant lesion.

Postoperative evaluation following corrective surgery is another frequent indication for arteriography, especially if surgical correction should fail to reduce the patient's blood pressure.

Techniques

Aortography can be performed by the intravenous, translumbar, and transfemoral routes. The latter is by far the procedure of choice. Its advantages include the low morbidity of the Seldinger percutaneous catheterization technique,[1] local anesthesia, and the use of large lumen catheters to deliver an adequate bolus of contrast medium very rapidly, thus allowing excellent visualization of all renal arteries even in patients with very rapid blood flow. In addition, with this technique the patient can be easily positioned for oblique projections, which are so valuable in the diagnosis of fibromuscular hyperplasia and atherosclerotic stenosis of the ostium of the renal artery. Its flexibility is further emphasized by its ability to replace the straight aortic catheter with a curved-tip catheter for selective renal artery studies.

---

[*] Read before the Minnesota Radiological Society Meeting, February 29, 1964, Minneapolis, Minnesota.

From the Department of Radiology, University of Minnesota Hospitals, Minneapolis, Minnesota.

[**] Associate Professor of Radiology.

[†] Medical Fellow in Radiology. National Heart Institute Trainee in Cardiovascular Radiology.

In older patients with severe atherosclerosis and tortuous iliac arteries where the retrograde passage of a catheter may be impossible, translumbar catheterization[2] is preferred. The aorta is punctured percutaneously in classical fashion under local anesthesia with a needle-catheter combination. Once the aorta is entered, the needle is removed, leaving the Teflon catheter in place. This catheter is then advanced in the aorta, allowing the use of a power injector without danger of subintimal injection. Injection is made during the Valsalva maneuver, thus decreasing cardiac output and enhancing contrast visualization of the distal aorta and its branches. Nevertheless, the diagnostic quality of aortograms obtained by translumbar catheterization is inferior to studies made by the transfemoral approach. Furthermore, hematoma formation near the prospective operative site cannot be avoided.

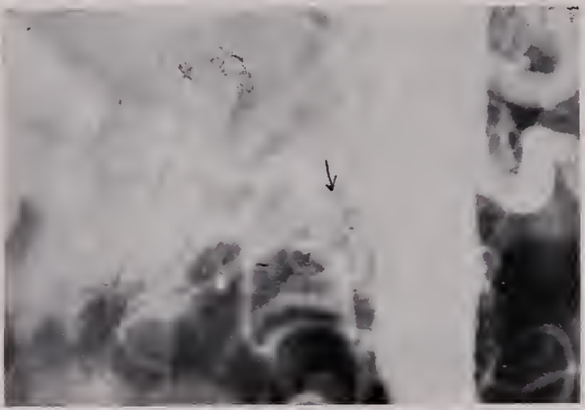

Fig. 1 — Renal artery stenosis due to atherosclerotic plaque. A. Demonstration of lesion on aortogram. B. Hemodynamic significance proven by pressure tracing during catheter pullback across area of stenosis.

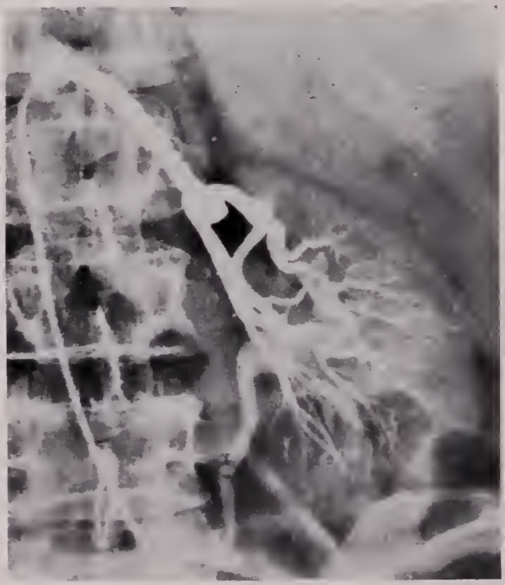

Fig. 2 — Fibromuscular hyperplasia. Typical accordion-like beading of renal artery.

Intravenous aortography does not yield sufficient concentration of contrast medium in the renal arteries for satisfactory interpretation of renovascular hypertension. Therefore, there is no place for this technique in the evaluation of renovascular hypertension.

Selective Renal Arteriography

The initial procedure should always be an aortogram, since this procedure allows visualization of the entire renal vascular tree on both sides. In addition, segmental renal arteries have been found to be of such frequent occurrence that an aortogram is mandatory in all cases.

However, once a vascular lesion has been seen, especially if it is of questionable nature, it is helpful to selectively catheterize the involved renal artery and obtain another arteriogram to eliminate disturbing superimposition of other arterial branches.

In addition, it may be possible to pass a minute catheter across the area of stenosis in order to record pullback pressures. This latter procedure is of particular value in the exclusion of hemodynamically insignificant lesions, thus eliminating unnecessary surgery.[3] Such a procedure requires considerable skill and carries the risk of postcatheterization thrombosis of the renal artery or its branches. Its use should be limited to patients with mild renal artery stenosis and otherwise normal clinical tests.

Angiographic Findings

The vast majority of patients with curable renovascular hypertension show obvious angiographic findings, usually consisting of marked narrowing of the main renal artery or its segmental peripheral branches.

Atherosclerotic Plaque

The most common cause of stenosis is atherosclerotic plaques. These occur in the older age group and are frequently found at the ostium of the renal artery or in its proximal third (Figure 1). The lesion appears as an eccentric "filling defect," which is especially well appreciated when seen in profile. Plaques seen "en face" appear only as areas of slightly decreased density, and can therefore be easily overlooked unless examination is repeated in an oblique projection. Occasionally, atherosclerosis will cause a diffuse narrowing of the artery. Stenotic atherosclerotic lesions may be seen in patients who are normotensive and in those who have essential hypertension; no patient should therefore be operated upon on the basis of the aortogram alone.

Fibromuscular Hyperplasia

Perhaps the second most common cause of renal artery narrowing is fibromuscular hyperplasia (Figure 2), a lesion that occurs in a younger age group. The typical angiographic finding is multiple areas of concentric narrowing. Between these narrow ridges or septa, there are areas of relative dilatation producing a beaded appearance. In about half of the cases, the lesion is bilateral. It is usually found in the middle and lateral thirds of the renal artery and may extend into smaller branches.

Coarctation of Renal Artery

Less commonly, congenital stenosis or coarctation of the renal artery may be

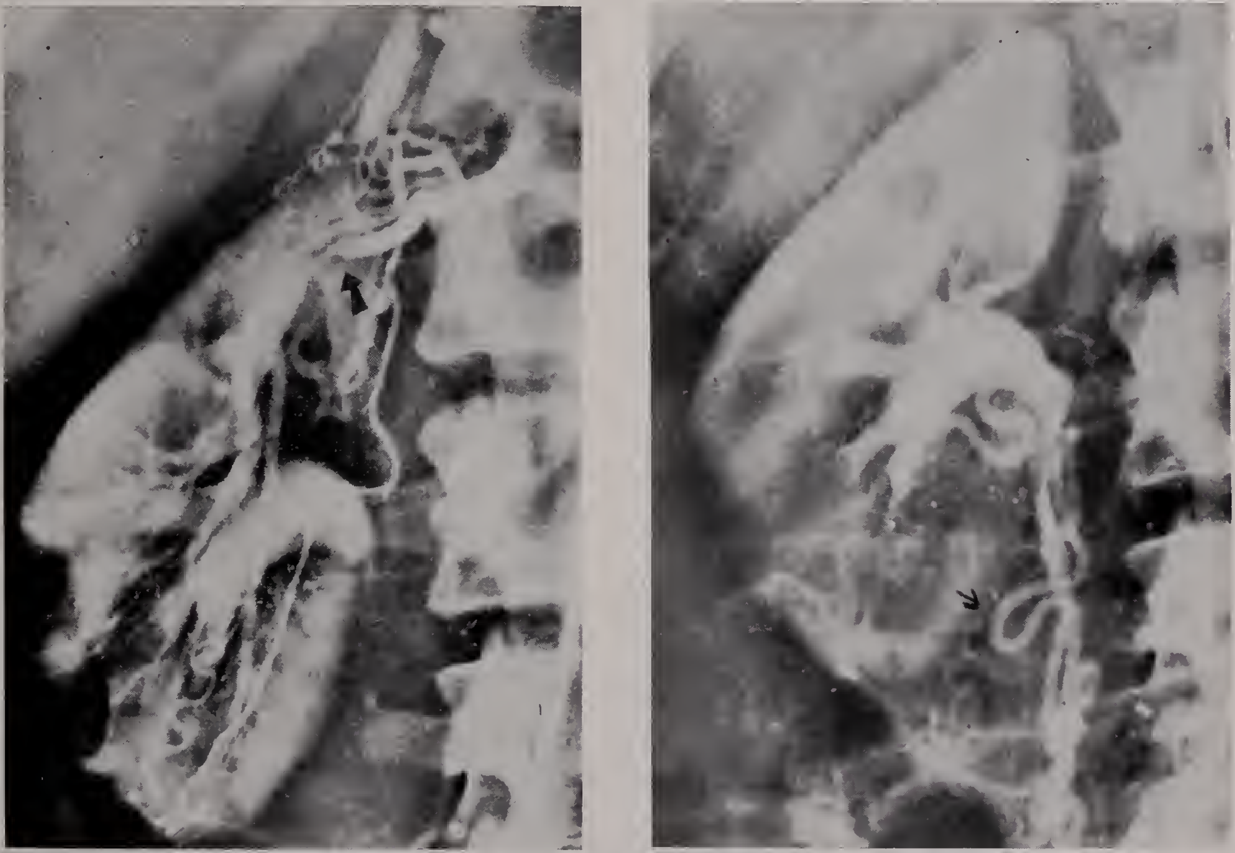

Fig. 3 — Complete occlusion of renal artery, likely congenital. (a-left) Demonstration of occlusion. (b-right) Collateral supply through ureteric artery. Contrary to common belief, complete occlusion of the renal artery with collateral supply may cause renovascular hypertension. This patient also had a positive urea washout urogram and was cured of her hypertension by surgery.

demonstrated. This is usually seen in children and young adults and has been considered by some investigators as a manifestation of fibromuscular hyperplasia. However, the angiographic appearance is quite different, since only a single area of concentric narrowing can be found (Figure 3).

Perinephric Disease

Perinephric constrictive disease, such as perinephric hematoma and fibrosis, may be a rare cause of curable renovascular hypertension. Thus, angiographic failure to demonstrate renal artery stenosis does not exclude the possibility of curable renovascular hypertension.

Pyelonephritis

In rare instances, pyelonephritis with scarring of renal parenchyma may result in ischemic water reabsorption and true curable renovascular hypertension.[4] It should be noted that the vast majority of patients with pyelonephritis and hypertension do not have curable disease.

Renal Artery Infarct

Renal artery infarction, although rarely followed by hypertension, may be well demonstrated angiographically. The occluded vessel may be evident on a study of high quality; selective renal arteriography is preferred because of its greater diagnostic accuracy.

Summary

Because it allows definite exclusion or anatomic delineation of lesions causing curable renovascular hypertension, renal arteriography is a most important diagnostic procedure. Transfemoral catheterization of the aorta is the technique of choice. Angiographic demonstration of renal artery narrowing alone does not imply curable hypertension; in all cases, the angiographic findings must be correlated with other clinical data.

Iron's Impact

The Iron Age, successor to the Bronze Age, gave impetus to the ingenious fashioning of many highly specialized instruments for the Roman surgeon's armamentarium. The workability and versatility of the new strong metal met the challenge presented by the multifarious wounds and injuries resulting from Rome's perennial engagement in wars of aggression and conquest.

According to Celsus, the inventory of more than 100 instruments available to Roman surgeons included "forceps, scalpels, amputation saws and trephines, syringes and probes, and a special instrument for removing pieces of bone after the delicate operation of trephining the skull. He also mentioned an ingenious instrument, an iron in the form of a letter V, to keep the ends of the wound apart when removing arrowheads."*

In our precious cabbage patches the holometabolous insecta are the hosts of parasitic polyembryonic hymenoptera, upon the prevalence of which rests the psychic and somatic stamina of our fellow countrymen. — William Osler

Recommended Dosage
of Lomotil Liquid
to Control Diarrhea

File:✓
Diarrhea

LOMOTIL®

Age	INITIAL LOMOTIL LIQUID DOSAGE*
3-6 mo.	½ tsp. t.i.d. (3 mg.)
6-12 mo.	½ tsp. q.i.d. (4 mg.)
1-2 yr.	½ tsp. 5 times daily (5 mg.)
2-5 yr.	1 tsp. t.i.d. (6 mg.)
5-8 yr.	1 tsp. q.i.d. (8 mg.)
8-12 yr.	1 tsp. 5 times daily (10 mg.)
Adult	2 tsp. 5 times daily (20 mg.) (or 2 tablets q.i.d.)

*Based on 4 cc. per average teaspoonful.
Note: After diarrhea is controlled the initial dosage can usually be reduced to meet the requirements of the individual patient.

LOMOTIL® TABLETS/LIQUID

Each tablet and each 5 cc. of liquid contains:
diphenoxylate hydrochloride ....2.5 mg.
(Warning: May be habit forming)
atropine sulfate ....0.025 mg.

Precautions
Lomotil is an exempt narcotic preparation of very low addictive potential. Recommended dosages should not be exceeded. Lomotil should be used with caution in patients with impaired liver function and in patients taking addicting drugs or barbiturates.

Cautions and Side Effects
Side effects are relatively uncommon but among those reported are gastrointestinal irritation, sedation, dizziness, cutaneous manifestations, restlessness and insomnia.

Lomotil is a brand of diphenoxylate hydrochloride with atropine sulfate; the subtherapeutic amount of atropine is added to discourage deliberate overdosage.

SEARLE *Research in the Service of Medicine*

to help relieve pain in common anorectal disorders

"non-caine"

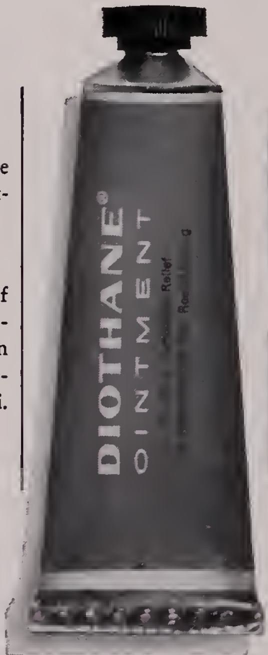
Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form...both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.



DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

Avulsion of Large Portion of the Scalp*

THE IMMEDIATE care of patients who have lost a large portion of the scalp involves the usual measures of controlling shock, hemorrhage, and pain. However, of special importance in this type of traumatic injury is treatment directed toward early skin coverage of the denuded cranium, thus preventing unnecessary scarring; this is especially true of the forehead where the eyelids can be severely distorted by cicatricial contractures. Ectropion of one or both upper eyelids is rather common when the application of skin grafts to the forehead is delayed; in fact, cases have been reported in which the ectropion was so severe that exposure of the globe resulted in loss of the eye. Occasionally, circumstances may be such that it is inadvisable to skin-graft the entire cranium in one operation; if such is the case, it is always preferable to skin-graft the forehead first, thus preventing in great measure the development of scar tissue that would distort the upper eyelids.

In cases of avulsion of a large part of the scalp, if raw surfaces and exposed bone are not covered with skin grafts but are allowed to granulate slowly and epithelialize spontaneously, the resultant scar tissue has a tendency to break down easily under the slightest trauma and to form an ulcer that may require weeks or months to heal. In addition, the possibility is always present that these scarred zones may undergo malignant degeneration.

In debriding the type of scalp wounds being discussed, shredded pieces of tissue are removed, loose flaps of skin around the periphery of the injured region are replaced and sutured, and torn bits of pericranium are unrolled, replaced, and sutured with fine catgut. Without waiting for a granulating surface to develop, I have found it helpful to proceed immediately with the application of split-thickness skin grafts obtained from the abdomen or thighs, providing that most of the periosteum is still intact. Moreover, if the wound can be grafted within a few hours after the injury, I do not hesitate to place thin split-thickness skin grafts directly over exposed bone even though some of the pericranium may have been lost. Fortunately, the greater part of such grafts usually takes satisfactorily.

If a patient with avulsion of large parts of the scalp is not seen for several days after the injury, free skin grafts applied directly over exposed bone and nonviable periosteum is inadvisable. In such cases, many surgeons believe that it is best either to drill holes into

the outer table of the denuded cranium or to chisel down the cortex until a bleeding surface is obtained. By such technics, bleeding areas lead to the development of granulations that grow to eventually cover all of the exposed bone. However, waiting for the development of such a granulating surface before skin grafts can be applied requires weeks or months, during which time dense scar tissue sometimes forms. Furthermore, when the entire wound is allowed to granulate before skin grafts are applied, the grafted areas often do not possess a smooth appearance but are rough and irregular. Instead of waiting for a granulating surface to appear, it often is preferable to chisel down the outer table of the cranial cortex until active bleeding is encountered, after which split-thickness skin grafts can be immediately applied. These grafts usually take well and result in a smooth, cosmetically acceptable surface. It is true, of course, that skin grafts placed directly on bone do not prevent sequestration of small zones of osseous tissue, which may come away as small spicules of dead bone weeks or months later.

Some surgeons advocate pedicle flaps of skin to cover the denuded cranium. However, skin flaps probably are best employed only after split-thickness skin grafts have been applied. Such grafts get rid of raw surfaces and consequently infection in the wounds. Moreover, in most cases, the split-thickness grafts make a satisfactory coverage, thereby eliminating the lengthy process of preparing pedicle flaps of skin.

Pneumomediastinum

IN REFERENCE to the article on Subcutaneous Emphysema by R. B. Tudor and Pablo Ramos* appearing in the November issue of MINNESOTA MEDICINE, certain comments seem apropos.

In adults, subcutaneous emphysema of the neck occurring secondary to mediastinal emphysema is most commonly due to perforation of either the major airways or the esophagus. This results from trauma to the thorax, during endoscopic or other surgical procedures, or as a result of foreign bodies.

Although spontaneous interstitial emphysema of the lung resulting in mediastinal and subcutaneous emphysema has been seen during labor, it is rarely recognized in the adult and appears to occur oftener among children with asthma and occasionally in the newborn. Undoubtedly this condition occurs many times without being recognized.

A clue to the presence of a pneumomediastinum on physical examination is a crunching sound heard synchronously with the heartbeat (Hamman's sign) on auscultation over the sternum. When the air spreads to the subcutaneous tissues of the neck it can be detected by gentle palpation.

Mediastinal emphysema can be recognized radiographically on the posteroanterior view of the thorax as a layer of air between the pericardium and the parietal pleura. On the lateral view increased radiolucency of the anterior mediastinum is apparent with retrodisplacement of the heart at times. The thymus may be more clearly outlined and there may be evidence of air extending up into the neck.

Obviously there must be a gradient in pressure which causes air, once it has escaped from the alveolus, to find its way along peribronchial and perivascular tissues to the mediastinum and often ultimately to the subcutaneous tissues. If we assume that mediastinal and intrapleural pressures are equal, this alveolar-mediastinal gradient approximates 5 to 10 cm. of water pressure during quiet breathing. Since, during quiet breathing, the mediastinal pressure is negative, air will not ascend initially to the subcutaneous tissues of the neck where pressure will be

*
She lost weight

*a result of 'METHEDRINE'® brand METHAMPHETAMINE HYDROCHLORIDE therapy

Her once unruly appetite is now well tamed with 'Methedrine' (methamphetamine hydrochloride)...an easy way to help control food craving and "hunger pains."

Side effects: Insomnia may occur if taken later than 6 hours before retiring. The usual peripheral actions of sympathomimetic amines (vasoconstriction and acceleration of the heart) are minimal and little noticed on low or moderate dosage.

Complete literature available on request from Professional Services Dept. PML

Contraindications and precautions: Should not be used in patients with myocardial degeneration, coronary disease, marked hypertension, hyperthyroidism, insomnia or a sensitivity to ephedrine-like drugs. Moderate hypertension in the obese is not necessarily a contraindication since it may be relieved as the overweight is reduced.

'Methedrine' brand Methamphetamine Hydrochloride: Tablets–5 mg., scored, in bottles of 100 and 1000.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, N.Y.

considered as being at atmospheric level. Indeed, the flow of air will be from the neck to the mediastinum, as is sometimes seen during tracheostomy or laryngeal operation, particularly if there is inspiratory obstruction. However, when the intrapleural-mediastinal pressure is increased above atmospheric pressure, as in asthma, coughing, or straining, the gradient between alveolar and mediastinal pressures will be no greater but there will be a definite gradient favoring the escape of air to the subcutaneous tissues of the neck. If such escape is not adequate, the mediastinal pressure will increase and impair venous return and, thereby, cardiac output. This situation demands prompt treatment consisting of needle aspiration of the mediastinum or surgical incisions above the clavicles to release the air as described by the authors. It is also apparent why treatment to decrease airway resistance, coughing and straining is helpful.

Solid Carcinoma with Amyloid Stroma

A case report in the January issue* calls attention to a rather uncommon type of thyroid carcinoma variously called solid carcinoma or medullary carcinoma with amyloid stroma. First described by Hazard in 1959, it is now a clearly defined subtype of thyroid carcinoma of a moderate degree of malignancy. During the past decades, classification of thyroid carcinoma has varied from undue complexity to oversimplification. In 1921, Wilson described no fewer than 17 cell types of thyroid cancer. More recently, many clinicians have grouped all thyroid carcinomas into two types: a slowly growing, rather innocuous variant and a rapidly growing, almost uniformly fatal form of the disease. Pathologists now recognize four main patterns of behavior in thyroid cancer.

The commonest type, papillary cancer, is seen especially in children and young adults. This tumor is frequently very invasive, spreading throughout much of the gland, and is often associated with massive bilateral lymph node metastasis. The tumor may actually spread directly through the thyroid capsule into adjacent structures such as the larynx or the trachea. Distant metastasis occurs rarely—usually in the form of a diffuse pulmonary infiltrate. In spite of this marked tendency toward extensive thyroidal infiltration and massive nodal metastasis, the disease is remarkably curable by surgical therapy. Very few deaths from this type of carcinoma have been documented, particularly in the younger age group.

A second form of carcinoma, usually slowly growing, is the encapsulated angio-invasive tumor often called follicular carcinoma. This variant only rarely involves regional nodes but spreads via the bloodstream to bones or lung. The prognosis is excellent in cases in which vascular invasion is minimal. For patients with marked invasion, the outlook is much more serious although the rate of growth of the tumor is frequently slow.

Anaplastic carcinoma, a term used to include a number of microscopic patterns, represents one of the most serious forms of cancer in humans. Almost all cases terminate fatally, usually in a matter of months.

Solid carcinoma with amyloid stroma is classified midway between the curable papillary carcinoma and the rapidly fatal anaplastic type. As in papillary carcinoma, the growth rate may be extremely slow, and regional lymph nodes usually are involved, sometimes extensively. In the gland itself,

**Depend on low-cost,
low-dosage Prolixin
— once-a-day**

Prolixin is a dependable tranquilizer that provides your patient with low cost therapy. No other tranquilizer costs less. Safe and convenient for office use—Prolixin in a single daily dose provides prolonged and sustained action. Markedly low in toxicity and virtually free from usual sedative effects —Prolixin is indicated for patients who must be alert. Clinical experience indicates fluphenazine hydrochloride is especially effective in controlling the symptoms of anxiety and tension complicating somatic disorders such as premenstrual tension, menopause, or hypertension—also useful for anxiety and tension due to environmental or emotional stress. When you prescribe Prolixin you offer your patient effective tranquilization that is low in cost, low in dosage and low in sedative activity.

THE SQUIBB TRANQUILIZER

WHEN TRANQUILIZATION WITHOUT SEDATION IS DESIRABLE, TRY

PROLIXIN®

SQUIBB FLUPHENAZINE HYDROCHLORIDE

SIDE EFFECTS, PRECAUTIONS, CONTRAINDICATIONS: As used for anxiety and tension, side effects are unlikely. Reversible extrapyramidal reactions may develop occasionally. In higher doses for psychotic disorders, patients may experience excessive drowsiness, visual blurring, dizziness, insomnia (rare), allergic skin reactions, nausea, anorexia, salivation, edema, perspiration, dry mouth, polyuria, hypotension. Jaundice has been exceedingly rare. Photo-sensitivity has not been reported. Blood dyscrasias occur with phenothiazines; routine blood counts are recommended. If symptoms of upper respiratory infection occur, discontinue the drug and institute appropriate treatment. Do not use epinephrine for hypotension which may appear in patients on large doses undergoing surgery. Effects of atropine may be potentiated. Do not use with high doses of hypnotics or in patients with subcortical brain damage. Use cautiously in convulsive disorders.

AVAILABLE: 1 mg. tablets. Bottles of 50 and 500.

For full information, see your Squibb Product Reference or Product Brief.

SQUIBB Squibb Quality—the Priceless Ingredient

SQUIBB DIVISION Olin

the tumor is circumscribed but not encapsulated and, as in papillary cancer, a clinically occult primary focus with positive palpable nodes may be present. Distant blood-borne metastases especially to viscera such as the liver are fairly common. Thus, the tumor is a much more dangerous disease than is papillary cancer. In the author's experience, approximately one third of all patients seen have died of their disease.

The surgical pathologist should be aware of the rather unique microscopic pattern of this carcinoma, either in a primary thyroid tumor or in a metastatically involved cervical node removed for diagnosis. The solid architecture with its absence of papillary structure or follicle formation may lead to an erroneous diagnosis of anaplastic carcinoma, resulting perhaps in failure to perform a potentially curative surgical procedure; or in the case of an involved cervical lymph node and a small or impalpable primary tumor in the thyroid, a needless search may be made looking for another more distant primary site.

Trauma and Social Conscience

THE ANATOMY of trauma is infinitely complex and touches us all. Male or female, hale or frail, no one of us lives free of the risk of accidental injury. Among increasing numbers of other bodies, we move about our world never knowing when the carelessness of one of us may lead to the damage of another of us. In this sense, each of us must be our brother's keeper. Prudent behavior must become an increasing part of social conscience.

This need is demonstrated on a nearby page, in the illuminating study by Doctors Gustilo, Foss, Leslie and Telander.[1] Accidents involving light-weight, highly-powered motorcycles have had an astounding increase in our metropolitan community. These motorcycles are usually rented, commonly by youngsters, who may be more or less rash and who lack the skill and experience needed for safe operation. Many of those injured are riding for the first time. Many of the injuries are severe, and frequently they are multiple.

As you read this article, consider the sum of years of lost life and of residual disabilities in the survivors of this group of young people. Question how many other citizens may have been injured in the forty-six accidents involving automobiles. Estimate the dollars of expense, the days and weeks of pain and anguish, the months and years of legal proceedings. Ask yourself how many of these accidents might have been avoided by even the simplest of safety precautions: Adequate instruction in the peculiar dangers of these machines.

The winter season enforces prudence in motorcycle operation. Hopefully, by spring, our social conscience may have a similar influence, through education, regulation, or restriction.

S. R. Maxeiner, Jr., M.D.*

In Fractures: B and C vitamins are therapy

Stress formula vitamins are a key factor in bone and tissue regeneration. To meet the increased metabolic demands, STRESSCAPS offers therapeutic amounts of B and C vitamins as an aid to smoother convalescence and earlier rehabilitation. In fractures, as in many other conditions of physiologic stress, STRESSCAPS vitamins are therapy.

Each capsule contains:

Vitamin B_1 (Thiamine Mononitrate)	10 mg.
Vitamin B_2 (Riboflavin)	10 mg.
Niacinamide	100 mg.
Vitamin C (Ascorbic Acid)	300 mg.
Vitamin B_6 (Pyridoxine HCl)	2 mg.
Vitamin B_{12} Crystalline	4 mcgm.
Calcium Pantothenate	20 mg.

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

The Editor's Soliloquy

Excuse My Errors

The editing of a manuscript for the "purpose of reviewing with the idea of assessing for the value of obtaining" an appraisal of the author who wrote that gibberish is an unenviable job. Extracting and eliminating the subjective I, my, and me, and the we, our, and us from the objective background requires unlimited patience and finesse.

Those sentences which start off confidently in one direction and then get lost; those dangling participles, loose phrases, vague antecedents, confusing tenses, inaccurate abbreviations without benefit of periods; those tautologic* passages and prolix paragraphs — all can add up to literary anarchy.

In a technical thesis where precision is required, only specific, concrete terms are acceptable.

An author may speak of a large hemorrhage or a small particle, but how large is large and how small is small? One can never be quite sure whether the writer means *my* large or *his* large, *my* small or *his* small.

After reading about a short-loop gastroenterostomy with an adequate stoma, this editor consulted the next ten surgeons he met, and learned that a 'short loop' might vary from 1 cm. to 2 ft., and an 'adequate stoma' might vary from the width of the index finger to 5 cm.

Then there are those contributors who bury the value of their manuscript in a long title which in itself constitutes a short summary of the whole study; justify their work in the introduction with the substantiating authority of a few dozen investigators, providing, in addition, gratuitous and sleep-inducing monotony with a thumbnail biography of each; proceed to elaborate and detail their study in the body of the manuscript; and then 'summarize' the whole by stating in effect: I am telling you that I have already told you in the preceding paragraphs. With these pleonasms the reader is tempted to give up. The title was too cumbersome to be advantageously catalogued; the introduction was too voluminous to be read; the body of the manuscript was too embellished with redundancies to compel interest; and the summary did not synthesize in capsule form.

Even with conscientious editing, however, it is often observed, in the finished product, that the editor himself, or the printer, or an assistant has slipped up. To air is humane. — oops! — C.O.R.

Stelazine® brand of trifluoperazine
will calm your anxious working patient—with little or no drowsiness

When anxiety interferes with work, your patient needs a drug that will calm without causing undue drowsiness. With Stelazine (trifluoperazine, SK&F), you can promptly control the anxiety without producing the sedation seen with certain other agents. Anxious patients can remain active during therapy.

Stoll[1] used the drug in 50 patients with anxiety, and noted: "There was no drowsiness in this group of patients and, because of their alertness and less impaired concentration, they were able to continue with and, in some cases, return to their daily work."

Stelazine (trifluoperazine, SK&F) produces a fast therapeutic response—often within 24 to 48 hours. The convenient b.i.d. regimen frees patients from the need for a midday dose.

Principal side effects, usually dose-related, may include mild skin reaction, dry mouth, insomnia, fatigue, drowsiness, dizziness, amenorrhea and neuromuscular (extrapyramidal) reactions. Muscular weakness, anorexia, rash, lactation and blurred vision may also be observed. Blood dyscrasias and jaundice have been rare. Use with caution in patients with impaired cardiovascular systems. *Contraindicated* in comatose or greatly depressed states due to CNS depressants and in cases of existing blood dyscrasias, bone marrow depression and pre-existing liver damage.

Before prescribing, see SK&F Product Prescribing Information.

Bronchoscopic Irrigation

QUESTION: Do you recommend bronchoscopic irrigation and aspiration shortly after surgical operation when a patient has developed a sudden rise in temperature, and the physical examination indicates a diminished aeration?

ANSWER: Bronchoscopic irrigation and aspiration is recommended during the early postoperative period if other simpler measures have failed to improve impaired pulmonary ventilation. Bronchoscopic aspiration during the early postoperative period has not been required in my practice during the past several years since intratracheal instillation of mucolytic agents (Mucomyst, etc.) have been employed routinely to stimulate the cough reflex and liquefy mucus plugs. These instillations are given every few hours through a small transtracheal plastic tube inserted percutaneously through a needle (Intercath or Venocath) and left in place for several days.

Butazolidin® in rheumatoid arthritis

brand of phenylbutazone

Geigy

Therapeutic effects
A number of workers have reported major improvement in 50-75% of cases, with some successful cases going into complete remission.

In responsive cases, improvement is generally seen within a week, so that trial therapy need seldom be continued beyond this period. Alleviation of pain is followed quickly by improvement of function and resolution of effusion or other signs of active inflammation. Relief of arthritic symptoms is quite frequently accompanied by increased appetite, gain in weight and an improved sense of well-being.

The initial response is usually maintained without dosage increases; indeed, initial dosage is often reduced for maintenance purposes.

Salicylate or steroid therapy can usually be diminished or, in some instances, eliminated.

Psoriatic arthritis responds in the same way as rheumatoid arthritis but the skin lesions are usually not affected either favorably or adversely by treatment.

Precautions
Before prescribing, the physician should obtain a complete history and perform a complete physical and laboratory examination, including a blood count.

The patient should be kept under close supervision and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools.

If coumarin-type anticoagulants are given simultaneously, the physician should watch for excessive increase in prothrombin time.

Side effects
The most common side effects are nausea, edema and drug rash. Infrequently, agranulocytosis, generalized allergic reaction, stomatitis, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug.

Contraindications
These include: edema, hypertension, or danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when other potent chemotherapeutic agents are given concurrently because of the increased possibility of toxic reactions; when the patient cannot be seen regularly; when the patient is senile.

Note: The physician should be fully aware of dosage, precautions, side effects and contraindications as contained in the complete prescribing information.

Fracture–Trauma Conference

Motorcycle Injuries

An Increasing Traffic Problem*

A distressingly large number of motorcycle accident victims have been treated in Minneapolis hospitals this summer. The recent surge in popularity of the motorcycle associated with the alarming number of injuries prompted this study.

Methods

This study is an analysis of motorcycle accidents at Hennepin County General Hospital and Methodist Hospital, covering a three-and-one-half month period from May 1 through August 15, 1964. A total of 200 accident victims were treated during this period: 121 cases at Hennepin County General Hospital and 79 cases at Methodist Hospital. The patients were first seen in the Emergency Rooms of the hospitals and evaluated. Definitive treatment was then given or the patient was transferred to another hospital of his choice. After reviewing the patient's record, each patient was sent a questionnaire inquiring as to the nature of the accident, the type of motorcycle used, the experience of the driver, etc.

Findings

Of the 79 patients seen in the Emergency Room at Methodist Hospital, 70 patients answered the questionnaire, while at the Hennepin County General Hospital, 53 of the 121 patients returned the questionnaire. Males were involved in the accidents four times as frequently as females. Twenty-four patients had been passengers on the motorcycle at the time of the accident. Ages ranged from three to 52 years, but the majority were 15 to 25 years of age (Table 1). Twenty per cent were riding the motorcycle for only the first or second time. Seventy per cent had either rented or borrowed the motorcycle (Table 2). Most of the patients seen in the suburban hospital had rented the motorcycle. All but six of the cyclists rode the light-weight motorcycles, such as Honda, Vespa, Yamaha, etc.

Continued

TABLE 1
Age Distribution of Motorcycle Accident Patients

	Hennepin County General Hospital	Methodist Hospital	Total
Under 10	1	1	2
11 to 15	12	9	21
16 to 20	52	37	89
21 to 25	42	14	56
26 to 30	8	3	11
Over 30	8	6	14

TABLE 2
Did You Own, Rent, or Borrow the Motorcycle?

	Own	Rent or Borrow
Hennepin County General Hospital	26	18
Methodist Hospital	19	51
Total	45	69

The exact nature of the accidents varied but could be classified into two general categories: (1) motorcycle upsets, (2) car-motorcycle collisions (Table 3). While more accidents were due to upsets, the more serious injuries occurred as a result of collisions.

TABLE 3
Nature of Accidents

1. Car-Motorcycle Collisions — 46 Cases — 38.4%
    - a) Collision with turning car.
    - b) Head-on collision with car.
    - c) Collision from rear by car.
2. Upsets From Various Causes — 79 Cases — 61.6%
    - a) Skid on road because of gravel.
    - b) Fell off for no apparent reason.
    - c) Lost control and turned over.
    - d) Accelerated too fast.
    - e) Motorcycle vs. motorcycle collision.
    - f) Unable to locate brake.
    - g) Caught fingers or feet on chains or spokes of wheel.
    - h) Hit immovable objects, post, etc.
    - I) Front wheel slipped.

The injuries were also classified as minor or major. There were 119 minor injuries and 72 major injuries in the study. Minor trauma included simple lacerations, sprains, contusions, etc., which did not require hospitalization and could be easily treated in the Emergency Room. The major category included fractures (simple, multiple, closed or open), traumatic amputations, large lacerations, cerebral contusions and intra-abdominal injuries which necessitated either hospitalization or immediate surgical intervention. Ninety per cent of the major injuries involved the lower extremities, consisting of single or multiple fractures of tibia, femur or pelvis. Two patients died as a result of their injuries; both had sustained skull fractures with brain damage.

Case Reports of Representative Injuries

Case No. 1

A 25-year-old machinist driving a Harley-Davidson motorcycle collided with a car making a left turn. The driver was thrown from the motorcycle and brought unconscious to the Emergency Room at Methodist Hospital. During the next half hour, his right pupil dilated and became fixed. Skull X rays revealed a skull fracture. At craniotomy an acute epidural hematoma was evacuated. Fractures of the left ankle, left tibia and right femur were also treated. A laceration into the left knee joint was sutured. Subsequently the patient did well and was discharged after five weeks' hospitalization with healing fractures.

Case No. 2

A 26-year-old typist riding his motorcycle home from work collided with an automobile. He arrived at General Hospital semicomatose, with a skull fracture, left femur fracture, compound left patellar fracture, left ankle fracture and compound right tibial fracture. He developed an acute abdomen which at exploratory laparotomy was found to be due to mesenteric hemorrhage. After a stormy hospital course, the patient was discharged seven weeks following admission in a spica cast with healing fractures.

The questionnaire revealed that 70% of the accident victims will not ride their motorcycles again (Table 4). Of 25 major injury cases at Methodist Hospital, only one person planned to ride a motorcycle again.

TABLE 4
Will You Ride the Motorcycle Again After the Accident?

	Yes	No
Hennepin County General Hospjital	22 — 41.6%	31 — 58.5%
Methodist Hospital	16 — 23.0%	54 — 72.0%
Total	38 — 30.9%	85 — 69.1%

Discussion and Conclusions

The public should be apprised of the hazards of operating motorcycles. The number of accidents due to upset of the machine points to the fact that it is basically an unstable vehicle. The popular light-weight machines are most frequently involved in accidents, a fact which may well be due to the inexperience of the driver as well as to the excessive speed and power of these machines in relation to their weight. Many patients commented that the rental agency involved provided inadequate instructions and orientation in the operation of the machine, and it would seem appropriate that some measures of control should be exercised in this regard.

Many accidents can be classed as the "low-speed type" where major injuries are sustained because the driver has little bodily protection on the motorcycle. Frequently motorcycle accidents occur because the driver of the automobile did not see the motorcycle. Some have resulted when the motorcycle was passing a car on the right side as the car made a right turn.

Fatalities from skull fractures and head injuries could probably be reduced by use of a protective helmet. There is no protection, however, to be applied for the extremities. The high incidence of arm and leg fractures in this study attests to the serious exposure of the cyclist to crushing forces. It would be prudent to insist that drivers of motorcycles receive special instruction and demonstrate proficiency in the use of these machines before venturing onto our highways and city streets.

Tumor Conference

Follicular Adenocarcinoma of Thyroid Gland

A lady, age 40, was admitted to Hennepin County General Hospital, having been seen in the E.N.T. Clinic with a complaint of stuffiness in the nose. At this time it was noted that she had an enlargement in the right side of the neck which appeared to include the right thyroid and lymph nodes, with a normal gland on the left side. A compete E.N.T. examination revealed nothing that could be considered a source of the enlarged nodes, either inflammatory or neoplastic, from within the nasopharynx itself.

The past history included an appendectomy at age 14 and a complete abdominal hysterectomy in 1962. There was no history of any medical disorders.

Physical Examination

The physical examination noted three palpable half to one-centimeter nodes in the right neck, located along the anterior border of the right sternocleidomastoid muscle. The right thyroid gland was firm and slightly enlarged and fixed to the trachea. While the patient was in the hospital, a repeat E.N.T. examination, including tonsillar biopsies, was done. Laboratory data included radioactive iodine uptake of 13.6% in 24 hours with a dose of 50 mc. of I 131, a PBI of 3.6 gamma per cent. Normal urine and hemoglobin of 13.9 grams; normal WBC and differential; pulse and blood pressure normal 80 and 110/76. A thyroid scan was done, showing no uptake in the right lobe and an essentially normal configuration of the left lobe, with the possibility of a toxic nodule.

Operation

A total right lobectomy, including the isthmus and approximately one half of the left lobe, was done with adjacent strap muscles and a right radical neck dissection, including the internal jugular and sternocleidomastoid muscle. The recurrent laryngeal nerve was preserved.

At the outset of the operation, upon exposure of the node-bearing area, one lymph node adjacent to the inferior portion of the right thyroid lobe was sent for frozen section. This appeared to be normal thyroid with some papillary appearance. After the specimen was removed, another frozen

Continued

section of the gland itself revealed a well differentiated carcinoma of the thyroid.

Pathological Report

Eleven of the twelve lymph nodes examined contained follicular structures. The thyroid tissue showed hyperplastic follicular elements generally filled with deep eosinophilic-staining colloid material. The cells of the glandular spaces were low cuboidal. There were areas of fibrosis as well as areas in which the glandular spaces contained no colloid, thus giving some distinct papillary appearance with large pale-staining cells and other small round follicles with no colloid. Approximately one half of the nodules contained definite lymph-node structure. The tail of the parotid gland contained no tumor.
Diagnosis: Follicular adenocarcinoma of thyroid gland with extension to lymph nodes.

Discussion of the Problem

A recommendation for future management and therapy is sought, with the following questions being posed:

1. In the absence of definite involvement or extension into the left lobe, should the remainder of it be removed or ablated on the possibility of future radioactive iodine uptake by metastases?
2. In case of local recurrence or distant metastases, what type of management would be recommended?

James Bascom, M.D.
Chief Surgical Resident
Lee Simso, M.D.
Surgical Resident
Hennepin County General Hospital

Commentary by Dr. Irving M. Ariel

Dr. Ariel was present at the Tumor Conference presentation of this case and has been kind enough to review his opinion. He had come to Minneapolis in November, 1964, to present a lecture to the Minneapolis Surgical Society, and another on the following day to the Minnesota Surgical Society. Dr. Ariel and Dr. Pack are coauthors of 12 recent volumes on cancer.

"I would consider this case a follicular cancer and treat it as such. The presence of the papillary elements would not influence my over-all approach. Follicular cancer comprises only between 10 to 15 per cent of all thyroid cancers, and metastases to lymph nodes are seen in about 30 per cent of patients when they first present themselves for treatment. This tumor is particularly prone to develop blood-borne metastases which will be found in approximately 45 per cent of patients. The five-year survival or even cure rate is about 66 per cent. In view of these data, I would believe that the right thyroidectomy and neck dissection are sufficient, and I would not be inclined to give any further therapy.

It seems to me that there was some mention that involvement was found in the opposite lobe and that this was treated by hemithyroidectomy. Here again, even though a conservative procedure was done for cancer involving a given lobe of the thyroid gland, it would be my reaction to do nothing but watch further developments. I believe that the patient has a good chance for cure.

However, if one were inclined to do something, and in view of the avidity of follicular cancer for radioactive iodine, one may very readily give a course of radioactive iodine to this patient. My own personal preference would be not to do so, even though I recall that in the discussion I did state that I would. This is simply a matter of personal preference, rather than an out-and-out standard for treatment practice. If one should decide to give the radioactive iodine, it would be a safe way of destroying any residual cancer within the gland. Rather than give a massive dose as some therapists do, it has been my policy to give between 20 and 30 millicuries about every two to three months until the patient has been rendered completely hypothyroid, at which point I give Cytomel. This course of therapy would also have the added advantage of treating any cryptic metastases which may exist. I would not resort to any further surgery.

The reason I would not be inclined to do anything is due to a lesson which I learned from George Pack many years ago to the effect: "Treat cancer where you find it." In view of the fact that you don't know whether or not you have cancer in the opposite lobe, you are treating a statistic. Furthermore, I'd like to know exactly what I am treating. Therefore, I would be inclined to subject this patient to a radioactive iodine scan every so often, scanning not only the thyroid region, but also the cervical region, as well as the lung and bone regions for possible metastases to other sites. Should these occur, then you will be armed with the knowledge of the nature of the particular tumor and treat it accordingly.

In case of recurrence, I would again treat this patient exactly as I would any cancer patient, sticking strictly to cancer tenet treatments. If a recurrence developed on the left side, I would then go ahead and perform a left thyroidectomy and radical neck dissection, as you did for the opposite side. This, of course, is contingent on the fact that there are no other metastases present elsewhere. If metastases are present, then I would be inclined to be guided by their extent and nature. If they are widespread, I would be conservative and inclined to depend upon a course of radioactive iodine therapy. If the local recurrence did not respond, then I would conservatively resect them. If they existed in the thyroid gland alone, I would remove the gland; if the patient had lymph nodes containing metastases, I would then do the neck dissection.

In my scanning, I would also include the brain, as this has been a frequent site of metastases in my experience.

I hope I have not been too confusing. I have tried to relate the standards of treatment as well as to interject my own personal beliefs and practices."

Instead of wasting so much on space, why not spend a few of those billions for oceanographic studies? The sea contains almost unlimited potential resources for the future — to provide for planet Earth's exploding population. After all, why risk a war with those terrible Martians? — C.O.R.

Come on, I'll walk you in.

That a smug gleam in your eye?

Could be. My problem hypertensiv
finally came around.

Malignant?

No, plain stubborn. Moderately severe. Grade II.

Use anything special?

Just Regroton. One tablet daily.

Regroton? Haven't tried it yet.

You're missing something.

Regroton®

Superior to other antihypertensives in 76 of 80 patients in a 2-year study*

Geigy

Composition: Each tablet contains chlorthalidone, 50 mg., and reserpine, 0.25 mg.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: Discontinue 2 weeks before general anesthesia, 1 week before electroshock therapy, and if depression or peptic ulcer occurs.
Precautions: Reduce dosage of concomitant antihypertensive agents by one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take particular care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side Effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.

Average Dosage: One tablet daily with breakfast
Availability: Bottles of 100 and 1000 tablets.

Neurological Conference

Herpes Zoster*

Today we are considering a case of herpes zoster in a man 58 years of age. Although the inflammatory involvement has been limited to his left face and eye, the degree of incapacitation has been great. Not only has he had to cease gainful employment, but he has been extremely uncomfortable because of severe pain. Beyond that, totally satisfactory recovery is still in doubt.

Dr. Robert Anderson**

The patient, who is 58 years old, had been in good health until July 10, 1964, when he developed a "pins-and-needles" feeling in the left side of his scalp. This unusual tingling persisted night and day for about one week before watery blisters appeared over the distribution of the ophthalmic division of the fifth cranial nerve. Hospitalization became necessary because of the severe pain in this area; there was also an inflammatory breakdown of the skin with weeping and crusting of lesions. Darvon Compound was used to control the pain, and occasionally thorazine was used to quiet the patient. Moist boric-acid packs were applied to the face. During this time he also developed a scratchy feeling in the left eye and blurred vision. Subsequently he was referred to the University of Minnesota Medical Center for the complicating eye involvement and persistent pain. Examination at the time of his visit to New Medicine Clinic revealed a pustular, crusting erythematous dermatitis of the left face, characteristically ending at the mid-line involving half his nose and extending into the left scalp. The conjunctiva of the left eye was markedly injected; the left cornea was clouded, and the pupillary light reflex on the left was reduced. The involved skin was hyperesthetic to stimulation.

There had been no exposure to chicken pox, although there may have been to shingles.

Dr. Richard Meyer†

The patient was admitted to the local hospital with severe keratitis and dermatitis over the distribution of the left fifth nerve. In the hospital his

†Family physician from Faribault.

eye was treated with ophthalmic ointments. Some relief was obtained but he still had a tremendous amount of reaction in the skin area over his left temple, much like a second degree burn. Weeping of the skin gradually ceased and his pain eventually moderated, although he continued to have typical attacks of sharp pain, which were intermittent and of short duration. We discharged him on September 12, after nine weeks' hospitalization, at which time he was relatively free of pain. After a week, however, the pain again became more severe and the conjunctivitis and keratitis worsened.

The pain that he had prior to his admission to this hospital was not as severe as the pain that he had had at the onset of his illness. It was considerably worse, however, than he had had at the time of his discharge from the local hospital.

There had been no evidence of a hearing impairment, but there were several episodes of what seemed to be a psychotic reaction during the last two or three weeks of his hospitalization. These episodes occurred intermittently, perhaps twice a week, and each lasted about six hours. He was given thorazine, 50 mg., intramuscularly every four to six hours. After sleeping four to six hours, he would awaken, appearing much improved. His wife called me about two weeks ago, after he had again become excited, irrational, and unable to recognize a number of his friends. He also became belligerent during this time. This episode lasted over two days and constituted quite an unusual departure from his ordinarily withdrawn behavior. There was never any amnesia associated with this unusual behavior.

Neo-cortone ointment, a combination of a steroid and neomycin, as well as neo-polycin ointment, which does not contain a steroid, were used.

Dr. Raymond Gingrich*

The patient had a typical herpes keratitis as well as inflammation of the uveal tract. His vision was only 20/400 in the left eye.

In the usual case of ophthalmic herpes zoster numerous white blood cells accumulate in the anterior chamber of the eye. Small blisters then develop over the cornea and eventually rupture. Concomitantly the cornea becomes over-hydrated and very painful, and vision is considerably decreased. Therapy is directed towards (1) reducing the inflammation, (2) dehydrating the cornea, and (3) preventing any sequelae of the inflammation itself. Steroids are very important for accomplishing these goals. Treatment of herpes zoster is different from treatment of herpes simplex. In the latter, they have isolated the virus directly from the vesicular lesions. Consequently, steroids are not used in herpes simplex in the early stage since further growth of virus may be encouraged. On the other hand, iododeoxyuridine, which is a deoxyribonucleic-acid analog, has been tried in herpes simplex with some success. The virus readily accepts this analog, which in turn prevents the virus from duplicating itself. This is probably the first drug that has been found to work effectively against the virus. Because of the inhibitory action of iododeoxyuridine, its use could permit the simultaneous employment of steroids in late herpes simplex. Otherwise, the use of steroids in herpes simplex is contraindicated because the cornea may perforate. Herpes zoster, on the other hand has not been shown to have any virus in the corneal lesions.

---

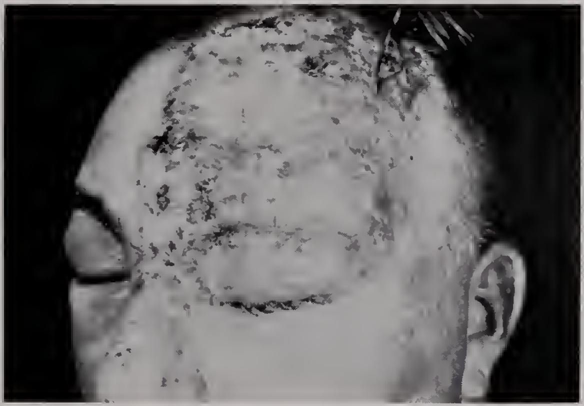
*Fellow, Department of Ophthalmology, University of Minnesota Medical Center.

Possibly the damage of herpes zoster may be a neurotrophic type due to an interruption of the nervous innervation. The cornea simply seems to degenerate much the same as the atrophy of muscle when a motor nerve has been severed, and a corneal ulcer may form.

We use cortico-steroids, both systemically and topically, to reduce the inflammation. Atropine solution is used locally to keep the pupil dilated, thus preventing adhesions between the lens and iris. The formation of adhesions could result in a complicating glaucoma by obstructing the outflow of aqueous humor. A dehydrating agent such as a 5% solution of cellulose gum can be used to remove excess fluid from the cornea. A protective shield may be placed over the eye to prevent external traumatic damage. Topical ophthalmic ointments are frequently used to prevent a secondary bacterial infection. All we can hope to accomplish is to reduce the severity of involvement and trust that the patients will improve by themselves.

ACTH could be used to advantage if an elevated steroid level could be maintained. Its use is somewhat controversial in our department. The concomitant use of ACTH with the cortico-steroids would help prevent atrophy of the adrenals.

The aseptic accumulation of white blood cells in the anterior chamber of the eye could have an allergic origin. Certainly herpes simplex is strictly a viral infection initially, but in a secondary reinfection of simplex there are deep plate-like lesions; this probably indicates hypersensitivity.



Herpes zoster of the ophthalmic division of the fifth cranial nerve.

Dr. John Brantner*

We had considerable difficulty with the psychological testing, mainly because it took more than one interview to complete the examination. The patient required hours to finish the multiphasic (MMPI). Basically he is a pleasant man to talk to, and one gets along comfortably with him. A curious aspect about him and his family is their frank acceptance of this unusual illness. His wife and son co-operate with him and try to do whatever they can, not becoming overly alarmed. My impression of the family is that they are calm, stable people. The patient has an IQ of about 80. I suspect that much of the family's apparent stability and strength could be partly due to an unawareness of the serious problems involved.

*Clinical psychologist, University of Minnesota Medical Center.

Continued

The patient himself is confident and hopeful. On minimal testing for organic brain damage there is a strong indication of some central involvement; however, I am not sure that this is related to his disease. He also shows pretty clear evidence of a psychotic-like adjustment. I cannot determine whether this is an organic or functional psychosis. In talking to him we have no definite clues concerning this; yet he described one hallucination which was perfectly vivid to him and lasted a couple of days. In it he saw a neighbor using several white horses, razing barns and wrecking his property. When the patient came out of this he was extremely startled to find that all the destruction that he thought he had observed had not actually occurred. His son and his wife understand and believe these episodes are due to his illness; they accept them and do what they can.

On the multiphasic the patient shows a psychotic pattern that does not occur frequently in either psychiatric or medical cases. In the medical cases it is associated with borderline psychoses with elements of withdrawal, anger, and hostility. There may be short periods of confusion, disorientation, and a characteristic apathy, shown by a willingness just to drift along. Frequently associated with this is a concern over physical health, although the physical complaints the patient refers to in the multiphasic certainly seem to be referable to his present disorder. From what Dr. Meyer stated, there may have been episodes of hallucinations prior to this illness, and we may be dealing basically with a border-line psychotic. There are some signs of organic brain damage, clear evidence of psychotic behavior, a multiphasic revealing a border-line psychosis, and evidence of limited intellectual ability.

Dr. Soll

This is interesting from the point of view that cerebral involvement may complicate herpes zoster. Seizures have been known to occur, and with this in mind we obtained an electroencephalogram; however, it was normal. The patient has potentially serious family problems regarding his work status. Would you tell us the results of your interview with the patient, Miss Kretchmer?

Miss Helen Kretchmer*

I interviewed the patient and his wife as a couple. They apparently present themselves as a couple wherever they go. She has accompanied the patient to every appointment since he has been coming to the University Hospitals.

The patient and his wife seem to be pretty close, since a question posed to one produced a response from both. During the interviews they were relatively passive, accepting individuals, at least superficially. They seem to enjoy each other and also the social aspects of their hospital contacts. The patient was very receptive to medical care here and had almost a mystic attitude toward his illness, relating it to his past illnesses and surgery. He feels that he has had a difficult time, but is confident that he will recover completely. He is currently on a six-month leave of absence from work, terminating some time in January, 1965, and he plans to be well by that time. His primary concern about the pain in his left eye seems to be reduced to a great extent, and his outlook seems to be quite cheerful now.

---

*Supervisor and assistant professor of social service, University of Minnesota Medical Center.

The patient went through elementary school, completing the sixth grade. The army rejected him twice because of a hernia, poor feet, and poor eyesight on the left. He and his wife were married when he was 22 and she was 21. They live in their own home, a duplex, which they value at about $8,000. I am giving a little detail on the financial situation, because I think there has been some concern about how they are going to manage until he returns to work. They have about $200 left to pay on the duplex on the basis of $10 a month. They rent an apartment at $15 a month to tenants who do all maintenance of the apartment. A son, aged 19, drives a truck and snow plow for the State Highway Department. The patient's mother-in-law, aged 90, also lives with them. She has had a stroke and was recently ill with "shingles." She is able to get around and loves to wash dishes, which the patient's wife allows her to do. Her income is $60.70 a month from Old Age Assistance. So they have little bits of income from various sources. Before the patient became ill he used to plow gardens. Actually their present income is limited to $100 a month from insurance carried by the company, although they don't know how long this will continue. The patient has worked 20 out of the past 26 years at one company, operating a carding machine, working in a warehouse, and most recently stocking, grading, and maintaining records. He is quite proud of having acquired a more responsible position. His income normally is about $60 a week and he expects to be eligible for social security at age 65. Their savings, about $600 from a former company pension, equals his local hospital bill. They had hoped to buy a furnace with that money, but now will be unable to do so. The patient does have some hospital insurance, supplemented by county authorization. Thus, since their needs are modest, I feel they are not really insecure. If he were not able to return to work in January, 1965, there might be a possibility of assistance from local agencies such as Aid to the Disabled, or from the welfare board. If he were permanently disabled, social security disablement could be considered.

Dr. Soll

From the neurological point of view, these are extremely difficult problems to treat. Herpes zoster, whether it be cranial-nerve or spinal-nerve involvement, almost invariably produces severe pain, sometimes even after the superficial skin lesions actually heal. During the acute phase, calamine lotion may be applied to the superficial lesions to promote soothing and drying. If the lesions are unruptured, collodion may be applied to prevent their breakdown. The pain is much more difficult to treat. Aspirin and codeine often afford relief, but sometimes more potent narcotics may be required. However, prolonged use of narcotics should be avoided. Often the use of deep X-ray irradiation to the nerve roots or trigeminal ganglion will alleviate the pain, but it should not be used during the acute phase of the disease. It is possible to approach the problem of persistent, unrelenting pain surgically if the zoster is of spinal origin. Section of the lateral spinothalamic tract above the level of the lesion can afford relief. Such a procedure cannot be done, however, when the cranial nerves are involved. ACTH or other cortico-steroids such as decamethasone during

Continued

the acute phase may prevent the postherpetic complications by reducing the inflammatory reaction.

Elderly people are frequently more debilitated by herpes zoster than younger individuals. The virus of herpes zoster is thought to be the same as the virus causing chickenpox. Cases have been reported in which herpes zoster and chickenpox have occurred simultaneously in different members of the same family, the children usually having chickenpox. This may mean that people who lose their immunity to varicella may become susceptible to herpes zoster as adults.

I think it would be interesting to ask the patient directly what his outlook is about getting back to work.

Dr. Soll: Do you recall, was your pain initially the same kind of pain as it is now?

Patient: It is the same kind of pain but not as bad.

Dr. Soll: Do you have a lot of trouble seeing?

Patient: Yes, I have trouble even seeing television. I usually sleep or listen to the radio.

Dr. Graham Beaumont:* How many pain pills are you taking each day?

Patient: About three or four.

Dr. Beaumont: Does the pain wake you at night?

Patient: That's the funny thing — I have good nights, but it begins to hurt again after I wake up.

Dr. Beaumont: What sort of work do you do?

Patient: I have to do some reading, weighing things — a lot of the work is pretty close up.

Dr. Soll

In summary, this 58-year-old patient has been incapacitated by herpes zoster involving the ophthalmic division of the left fifth cranial nerve for the past three and one-half months. The chief complications have been persistent pain and a severe ophthalmic keratitis which has markedly reduced the vision in his left eye. Non-narcotic analgesics have controlled the pain fairly well. Cortico-steroids are being used locally and systemically to control the keratitis of the left eye. Psychologically there is suggestive evidence of organic brain involvement. The social-service interview reveals that the financial status is meager but probably adequate for the time being. The patient's capability of returning to work will depend greatly on his response to treatment in the next few weeks; this response, in turn, will determine what further efforts will need to be done both medically and by social welfare.

Advances

Infections of the Urinary Tract

Part IV. Antibacterial Regimens*

WILLIAM J. MARTIN, M.D.**
RICHARD D. WAGONER, M.D.**
Rochester, Minnesota

IN THE management of infections of the urinary tract, the individual situation may influence selection of the drug to be used; vomiting may disallow use of usual therapy if that therapy ordinarily is given orally. Previous allergic reactions or current intolerance of an agent may disqualify it for use.

Renal insufficiency makes mandatory the careful use of certain drugs that are either nephrotoxic or potentially toxic to other organ systems. When resistant organisms are encountered, the intrinsic severity of the infection is the keystone to deciding whether the risk associated with the use of more toxic antimicrobial agents is justified.

Acute Simple Infection

Since acute simple infections are common, may be transient, and seldom require heroic therapy, treatment may be initiated after preliminary identification of the bacteria by the examination of a stained preparation of the urinary specimen. In this regard, acute uncomplicated infections often have appeared to subside without specific treatment. Failure to eradicate the infection requires further study, including urologic and microbiologic, to exclude predisposing disease, an underlying lesion, resistant organisms, and so forth.

As a general rule, bacteriostatic agents, including those that are not antibiotics, are used in acute simple infections. For the more serious or complicated infections, bactericidal agents may be preferable, with consideration of the usual limitations of drug toxicity and routes of administration. Nonantibiotic antibacterial agents currently used in the therapy of acute simple urinary infections include (1) the sulfonamides, (2) nitrofurantoin (Furadantin), (3) nalidixic acid (NegGram),[19] (4) methenamine mandelate (Mandelamine), and (5) acidifying agents such as methionine.

If the physician is convinced that there is an acute, uncomplicated urinary infection, he may wish to use a sulfonamide because of its low cost and ease of administration. Sulfonamides may be given in amounts of 0.5 to 1 gm., four times daily. In other patients, such as those allergic to sulfonamides, nitrofurantoin in amounts of 50 to 100 mg., four times daily, may be preferred. In some of these latter patients who have infection due to coli-aerogenes or Proteus organisms, nalidixic acid may be elected in amounts of 0.5 to 1 gm., four times daily by the oral route. In certain infections, especially enterococcal, methenamine mandelate may be used in amounts of 0.5 to 2 gm., three or four times daily. The mandelic acid component of methenamine mandelate helps acidify the urine, releasing formaldehyde from methenamine. The formaldehyde is antibacterial to both gram-negative and gram-positive organisms, and bacterial resistance probably is not a problem. However, despite the mandelic acid component, supplemental acidification may be required, particularly with urea-splitting organisms.

Decrease of urinary pH and of bacterial

Continued

---

*See Part I, Minnesota Med., January issue, Page 95, Part II, February issue, Page 231, Part III, March issue, Page 379.

**Section of Medicine, Mayo Clinic and Mayo Foundation.

counts in the urine may follow the use of 8 to 15 gm. of methionine daily; however, when more than 8 gm. is given per day, the patient may complain of the odor of hydrogen sulfide about his person. The sulfur in methionine is oxidized to sulfate and is excreted in the urine, making it acid. Other acidifying agents such as ammonium chloride, ammonium mandelate, calcium mandelate, and ascorbic acid have been given in conjunction with methionine; if urinary pH can be reduced to 5 or less, the desired antibacterial effect may be procured, but it is difficult to maintain the desired pH without inducing metabolic acidosis. In short, the physician may avoid giving more than 8 gm. of methionine daily by using in addition another agent such as ammonium chloride, so as to decrease the likelihood of inducing the odor of hydrogen sulfide. Also metabolic acidosis may be avoided by giving, in addition to the acidifying agents, methenamine mandelate. Use of an acid-ash diet or of hippuric acid (which is present in cranberry juice) are not currently in common use. When attempts are made to keep the urine acid, the physician considers restricting the patient's fluid intake to 1200 ml. a day and the avoidance of foods, primarily citrus fruits, and drugs, such as sodium bicarbonate and milk of magnesia, which increase the alkalinity of the urine. Also, the patient should periodically determine, by means of nitrazine paper, whether his urine is properly acidic.

Recurrent Infection

Nonantibiotic antibacterial agents may also be used when extensive investigation is unrewarding and yet infection continues to recur; 0.5 gm. of a sulfonamide, 50 to 100 mg. of nitrofurantoin or 0.5 to 1 gm. of nalidixic acid is given two to four times daily for five to 10 days monthly for several months. Such a procedure may serve to prevent further recurrences.

Recurrent infection in the absence of demonstrable underlying uropathy or predisposing disease may not necessarily represent a series of unconnected and isolated episodes. Rather, the exacerbations may represent reactivation of temporarily quiescent bacteria that have continued to dwell in the urinary tract. However, while definitive knowledge is lacking, repeated episodes of infection probably reflect reinfection, relapse, and superinfection in decreasing order of incidence. Micro-obstructive changes within the nephron due to prior infection may enhance the possibility of future infection. Recurrences of infection are usually due to reinfection with new strains presumably from the fecal flora contaminating the perineum. Antibacterial prophylaxis may provide an infection-free interval during which the patient's tissues may develop greater resistance to potential infection in the future. Attempts at antibacterial prophylaxis are usually made for at least six months following control of the preceding infection; after this time, prophylaxis may be discontinued in the hope that further medication will not be required.

Chronic Infection

The nonantibiotic agents, except possibly nitrofurantoin, may also have application in certain chronic infections in which underlying uropathy is uncorrectable or more heroic therapy has proved ineffective. Intermittent or continuous administration of these agents in such cases may minimize the patient's symptoms, and in some cases sterilization of the urine ultimately is achieved. In patients with chronic infection, suppressive therapy may be continued indefinitely, especially if exacerbations are thereby lessened, in the hope that the degree of progressive renal damage is being reduced. In these latter patients, such therapy more often is intermittent; for example, it is given the first week of each month or every other week rather than continuously. Use of nitrofurantoin in some of these patients is avoided because therapy is prolonged and decreased renal function is common; both of these factors might enhance the likelihood of nitrofuran neuropathy.[20] In this regard, the manufacturer of nalidixic acid recommends that the drug be given cautiously in patients with renal impairment. Also, methenamine mandelate should not be given to patients with renal insufficiency. Even use of the acidifying agents in the presence of renal insufficiency is not without hazard.

Persistence of infection in this group appears to be more often related to the structural and physiologic abnormalities of the urinary tract than to the drug employed. Thus, the pertinence of an antibacterial regimen is not well evaluated on the basis of its ability to render the urine permanently sterile.

Severe Infection

Often in more serious urinary infections, other agents must be used. Severe urinary infections mean those that are characterized by a violent systemic reaction, those that persist after recent surgical correction of underlying uropathy, those in which renal function appears to be seriously threatened, abscesses, and the like.

Severe Gram-Negative Bacillary Infection

Up to the present, combined streptomycin-tetracycline therapy has been preferred in serious infections due to gram-negative bacilli prior to report of sensitivity tests. Use of ampicillin or cephalothin in infections due to E. coli; ampicillin, cephalothin, novobiocin, or penicillin in infections due to Proteus mirabilis; cephalothin in Proteus infections including those due to the mirabilis strain; polymyxin B or sodium colistimethate (Coly-Mycin injectable) in Pseudomonas infection; and chloramphenicol, cephalothin, or ampicillin in Salmonella infections may be considered if the patient's course and in vitro susceptibility tests so indicate. The newer antibiotic, sodium colistimethate, although less efficient weight for weight than polymyxin B, is also described as being less toxic; but this is disputed.

Streptomycin-tetracycline treatment given empirically for serious infections due to gram-negative bacilli has been preferred for several reasons. The onset of bacterial resistance may be delayed by the use of multiple antibiotics and enhanced effect obtained; and when such treatment is given before susceptibility tests are reported, broader antibiotic coverage is provided. Also, there may be discrepancies between bacterial susceptibility as determined by in vitro tests and that observed clinically involving one or both drugs.

In infections due to gram-negative bacilli not responding to tetracycline-streptomycin, susceptibility tests to chloramphenicol and kanamycin also may be procured with a view of substituting one or both agents. Chloramphenicol-kanamycin is not used routinely in the empiric management of gram-negative bacillary infection because these agents have greater potential toxicity than tetracycline-streptomycin. Also rarely, polymyxin B or sodium colistimethate is used in gram-negative bacillary infections other than those due to Pseudomonas organisms if the infections are not responding readily to streptomycin-tetracycline therapy.

Disadvantages accruing to the empiric use of tetracycline-streptomycin therapy are possible; but these are also possible with alternative antibacterial agents. The disadvantages include the dual depressive effect on the gram-negative elements of the flora, making coccal superinfection more likely. Streptomycin, kanamycin, and polymyxin B are nephrotoxic; streptomycin and kanamycin also are ototoxic, and polymyxin B may cause cerebellar ataxia. Periodic study of smears and cultures of the sputum and stools during antibacterial therapy may reveal change in the flora and impending superinfection.

Ampicillin, the semisynthetic orally administered agent, appears to have use in infections due to strains of E. coli, Salmonella, and Proteus.[19] The drug is ineffective against Pseudomonas and Klebsiella organisms. Although active against gram-positive cocci, it is less so than penicillin G and is ineffective against penicillin G-resistant staphylococci.

Cephalothin, a semisynthetic derivative of cephalosporin C is given intramuscularly.[19] Cephalothin resembles ampicillin in that it is active against strains of gram-negative bacilli and gram-positive cocci, and in addition against penicillin G-resistant staphylococci. It is ineffective against pseudomonades and some enterococci.

Gentamycin is another drug being investigated.[19] It resembles neomycin and kana-

Continued

mycin in its antibacterial spectrum and toxicity but may be more effective against Pseudomonas organisms than either neomycin or kanamycin.

Severe Streptococcal Infection

Combined penicillin-streptomycin therapy is indicated for serious infections due to enterococci, for example, Str. faecalis. Infections due to other strains of streptococci such as Str. pyogenes and viridans may respond to treatment with penicillin alone. In persons allergic to penicillin, erythromycin is the drug of choice.

Severe Staphylococcal Infection

The treatment of staphylococcal infections depends largely on results of bacterial susceptibility tests. If staphylococci are sensitive to penicillins G and V, these remain the drugs of choice; in mild infection, orally administered penicillin V has been successful. Potassium phenethicillin (Syncillin, Darcil) and penicillin V can be used interchangeably. There is cross-resistance among penicillins G and V and phenethicillin.

Among the commercially available antistaphylococcal semisynthetic penicillins there are sodium methicillin (Staphcillin), which must be given parenterally, in addition to sodium oxacillin (Prostaphlin) and nafcillin (Unipen), which can be given either orally or parenterally. These drugs retain their antibacterial activity in the presence of staphylococcal penicillinase and hence remain effective against staphylococci resistant to other penicillins. However, none of them is automatically the drug of choice in all urinary infections due to staphylococci resisting other penicillins. This is so because other effective, orally absorbable, and less toxic antibiotics are available, and because of the physician's desire to limit the use of the semisynthetic antistaphylococcal penicillins so as to minimize staphylococcal resistance to them. Unfortunately there is cross allergenicity among these agents and the other penicillins.

Generally, erythromycin is used when the organism is sensitive to it and resistant to penicillins G and V or when the patient is allergic to penicillin, since erythromycin can be given orally and is virtually nontoxic. When staphylococci resist erythromycin, lincomycin might be considered since it is orally absorbed. Use of the propionyl ester of erythromycin and triacetyloleandomycin is often avoided in the treatment of infections of the urinary tract because control of the process may require two weeks or longer and the drugs given for such periods may prove hepatotoxic.

Lincomycin is said to be bactericidal, but it may be hepatotoxic and perhaps hematotoxic. All staphylococci do not appear to be sensitive to its action. Thereafter, use of novobiocin might be considered.

If erythromycin, lincomycin, or novobiocin cannot be used, then a semisynthetic antistaphylococcal penicillin may be the drug of choice. If such a drug is not applicable as in patients who have previously exhibited allergy to penicillin, cephalothin may be tried. Although both kanamycin and vancomycin are toxic to the eighth cranial nerve, kanamycin may be considered before vancomycin, since kanamycin is given intramuscularly and vancomycin must be given intravenously. Chloramphenicol follows vancomycin in the list of selections, even though it has the advantage of being orally absorbable, because of its propensity to depress the marrow, and it is considered before ristocetin, which can also depress the marrow but which has the added disadvantage of requiring intravenous administration. Before or after consideration of chloramphenicol and ristocetin, depending on the fear of ill effects on the marrow as well as on the laboratory facilities available, combined antibiotic therapy can be considered. In attempts at combined therapy, however, the staphylococcus organisms should be susceptible on in vitro testing to both agents used. In such therapy a bacteriostatic agent such as erythromycin, novobiocin, or chloramphenicol might be employed with such bactericidal agents as bacitracin or neomycin.

The physician hesitates to use the tetracyclines in hospitalized patients because of the superimposed infections with resistant organisms that may ensue. Streptomycin has limited application as an antistaphylococcal agent, since staphylococci rapidly develop resistance to it. Polymyxin B, colistin, the sulfonamides, nitrofurantoin, nalidixic acid, methenamine mandelate and acidifying agents such as methionine have virtually no application in the treatment of serious staphylococcal infections.

When severe staphylococcal urinary infections demand treatment before the results of susceptibility tests are available, an agent can be given that previous experience has shown the staphylococci will most likely not resist. Methicillin or an allied drug, cephalothin, or vancomycin might be selected, and after 24 to 48 hours, when the results of susceptibility tests are known, the physician may be able to substitute a more pertinent or less toxic antibiotic.

Other semisynthetic antistaphylococcal penicillins under investigation are cloxacillin, dicloxacillin and diphenicillin. Cloxacillin on oral administration gives higher serum levels than oxacillin. Dicloxacillin gives levels twice as high as cloxacillin and four times as high as oxacillin. Diphenicillin also can be given orally and has been said to compare favorably with oxacillin.[19] Sodium fusidate also diphenicillin is being investigated as an antistaphylococcal agent.[19]

Severe Polymicrobic Infection

In serious infections due to multiple organisms, several drugs may have to be given simultaneously. The physician might give penicillin along with streptomycin in infections with Str. faecalis and simultaneously give a tetracycline to combat E. coli. Since it is difficult to say which organism is most important in such infections, broad coverage is necessary since estimation of the infectious capabilities of the individual organisms may be erroneous. Ampicillin may have special use in polymicrobic infections; cephalothin also warrants consideration in this regard.

Two Cases of Serendipity*

In the biological sciences serendipity has been quite as consequential as in the physical sciences.

Pasteur was led by chance to his method of immunization. One day an old and forgotten bacterial culture was being used for inoculating fowls. The fowls became ill but did not die. This happening was illuminative. Possibly by first using cultures that had little virulence and then repeating the injections with cultures of greater virulence, the animals could be made to develop resistance to infection gradually. His surmise proved correct.

In the late eighties of the last century, von Mering and Minkowski were studying the functions of the pancreas in digestion. While attempting to secure more evidence they removed that organ from a number of dogs. By good luck a laboratory assistant noticed that swarms of flies gathered round the urine of these animals, a fact which he mentioned to the investigators. When the urine was analyzed, it was found to be loaded with sugar. Thus for the first time experimental diabetes was produced, and the earliest glimpse was given into a possible cause of that disease. (Walter B. Cannon)**

Grand Rounds

Salicylate Intoxication

Though many new pharmacologic products have been made available, salicylates continue to play a prominent role in medical therapy. This compound and its derivatives are used in the treatment of rheumatism and gout, as antipyretics, keratolytics and analgesics. Because of their widespread use and ease of purchase, the annual consumption of salicylates indicates that they constitute some of the most extensively used medications in the United States. Used properly, salicylates are effective and rarely cause harmful or fatal reactions. However, in excessive dosage, the possibility of intoxication exists. The May 1961 Newsletter of the National Clearinghouse of Poison Control Centers recorded approximately 166,000 cases of salicylate intoxication.[1]

Absorption

Acetyl salicylic acid is absorbed from the stomach at a rate comparable to that of ethanol. It has been shown that in acid gastric fluid, salicylates return to an unionized salicylic acid form.[2] The unionized compound is then absorbed by a process of passive diffusion from the gastrointestinal tract.[13] The use of an alkalinizing agent, which raises the pH of the gastric juice, decreases the rate of absorption of salicylates. There is evidence that any factor which increases the rate of gastric emptying will increase the absorption rate of salicylates. An augmented absorption rate has been found to occur when the substance is administered with large volumes of fluid.[2] After salicylate is absorbed into the plasma, it moves into the tissues. However, since the rate of absorption into the plasma is much faster than its removal by the tissues, there is a disproportionately high plasma level of serum salicylate after ingestion.[3] In normal individuals, the peak plasma salicylate level occurs about one hour after oral ingestion.[4]

Excretion

The excretion of salicylate is primarily through the kidneys. After its absorption from the upper gastrointestinal tract, salicylate can be found in the urine within twenty minutes.[4] Studies done on the degradation,

---

Presented as a Medical Grand Rounds at Mt. Sinai Hospital, Minneapolis, November 24, 1964.

Continued

conjugation and excretion of salicylate show that approximately 70 to 80% is excreted in the urine in the form of free salicylate and its metabolites. A portion of the salicylate is bound to serum albumin, while the rest diffuses throughout the body water. Detoxication is accomplished in part by conjugation with glycine and glucuronic acid, with excretion in the urine in this conjugated form.[4] Approximately 20% of salicylate is excreted unchanged, 50 to 55% as salicyluric acid, 1% as gentisic acid, and 15 to 40% as glucuronic acid conjugates.[5] The excretion of free salicylate is increased in an alkaline urine. When the pH of urine is 7.5 or greater, 80% of the salicylate is excreted in the free form.[4]

Toxicity

Most surveys have shown poor correlation between serum salicylate level and severity of toxicity. There is no single toxic dose for all individuals. In some persons, levels as low as 20 mg.% have resulted in fatal intoxication, whereas other individuals are asymptomatic at the same serum level.[4] Nausea, vomiting, erythema, deafness and tinnitus have been associated with serum levels of 20 to 30 mg.%. At levels of 30 to 40 mg.%, albuminuria, profuse sweating, vertigo and hyperventilation have been recorded. Stupor, confusion, dyspnea and pulmonary edema begin at levels from 40 to 50 mg.%. In general serum levels greater than 50 mg.% are invariably toxic.[7]

Clinical Severity

Done[8] attempted to categorize the severity of salicylate intoxication on clinical grounds without reference to salicylate levels, as follows: 1. *Asymptomatic* — Subjective but no objective manifestations. 2. *Mild* — Mild to moderate hyperpnea, sometimes lethargy. 3. *Moderate* — Severe hyperpnea, prominent neurologic disturbance (marked lethargy and/or excitability) but neither coma nor convulsions. 4. *Severe* — Severe hypernea, coma or semicoma with or without convulsions. He felt that the variable of time determined the relationship between salicylate level and the severity of intoxication. Experiments following the oral ingestion of aspirin showed that the decrease in serum salicylate level approximated that of a first-order reaction. Beyond three hours, the serum salicylate level was found to decline at a constant fractional rate which did not change over twenty-four hours.

With the knowledge that the serum salicylate level at a given time could be accurately determined, and that the disappearance of salicylate from the serum was a first-order reaction, the half life of the circulating salicylate could be calculated. Half-life values, which ranged from fifteen to twenty-nine hours with a mean of twenty hours, were obtained. This made possible the extrapolation of the salicylate level back to zero time (So). Done then compared the clinical findings with the calculated So values. The correlation between the salicylate level at So and the severity of toxicity was excellent.

1. Asymptomatic	So 36 — 69 mg.%
2. Mild	So 56 — 89 mg.%
3. Moderate	So 84 — 111 mg.%
4. Severe	So 130 — 142 mg.%
5. Fatal	So 160 — 183 mg.%

From this study, it was concluded that a fatal outcome was inevitable in patients with an So value greater than 160 mg.%, unless rapid decrease was accomplished.

With the average rate of elimination of salicylate determined and with the relationship between So and the severity of intoxication established, a nomogram (Figure 1) was derived, making it possible to determine the expected severity of intoxication from the measured serum salicylate level at a given time after ingestion. The nomogram is not applicable to persons who have ingested salicylate in more than one dose. It is also unreliable in persons who excrete salicylate either faster or slower than average. The nomogram begins at six hours because earlier than this, the measured salicylate level approximates the So level and can be used directly in predicting the severity of intoxication. The use of the nomogram is of value in determining when vigorous therapy is necessary.

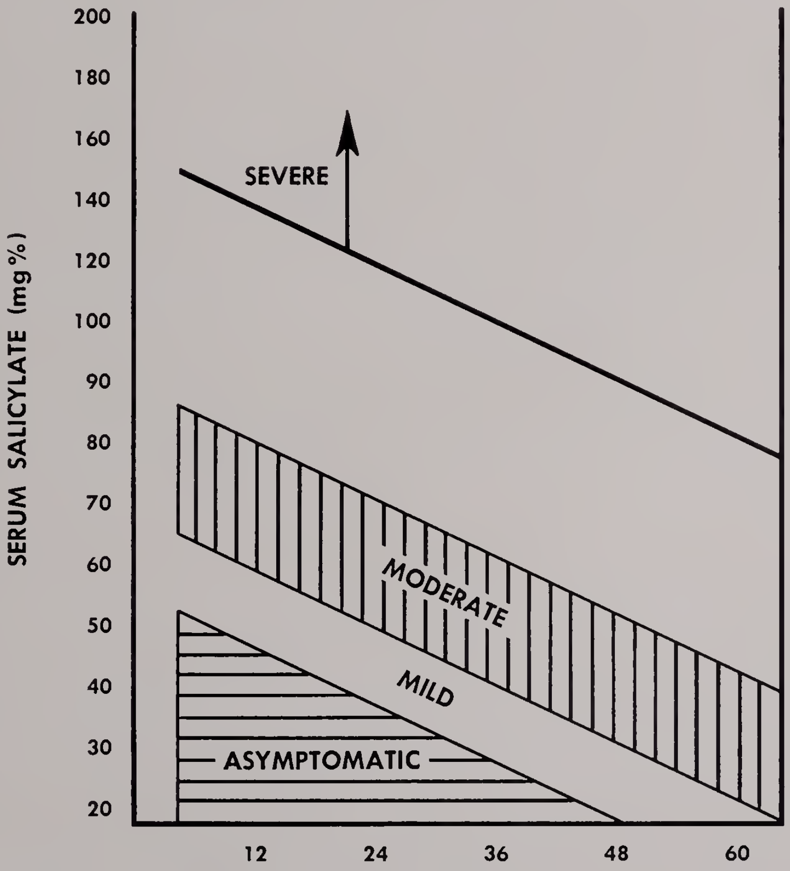

Fig. 1 — Nomogram of serum salicylate levels extrapolated from known level at any time after ingestion.*

Hyperventilation

Most clinicians regard hyperpnea as a valuable early sign of salicylate intoxication. Graham and Parker found that the hyperpneic action of salicylates was not seen if the serum level was below 21 mg.%. They felt that this toxic manifestation became evident at a serum level of 33 mg.% or higher.[9]

Continued

The mechanism producing hyperventilation secondary to salicylate intoxication has been investigated extensively. Initially it was thought that a transient lowering of blood pH initiated hyperpnea.[10] However, in experiments with animals, a transient lowering of the pH could not be demonstrated prior to the onset of hyperventilation. Stimulation of respiration was noted before the plasma CO_2 combining power began to fall. It was also observed that large doses of alkali failed to inhibit the stimulating action of salicylate on respiration.[9]

Other experiments indicated that neither the extirpation of the carotid bodies nor the administration of atropine abolished the stimulatory action of salicylates. However, when bilateral vagotomy was done, salicylates failed to produce hyperpnea. It was concluded that hyperventilation was due to the reflex stimulation of the respiratory center through the afferent fibers of the vagus nerve.[9]

A direct stimulating action of salicylates on the respiratory center was also demonstrated. This action was shown to be independent of the aortic and carotid chemoreceptors. When low concentrations of salicylates were applied directly to the region of the medulla by a needle in the cisterna magna, a rapid and dramatic increase in ventilation occurred.[10] It was also observed that the anterior hypothalamus was able to mediate the action of salicylates on respiratory stimulation.[11] A lesion in this region was capable of reducing or abolishing the stimulatory effect of salicylates.

Tenny and Miller have concluded that the respiratory response to salicylates is due to a direct central stimulating action and to the increased metabolic production of CO_2.[10]

Eichenholz et al. believe that the initial hyperventilation is due to the stimulatory effect of salicylates on the medullary respiratory center.[12] They concluded that the hyperpnea which persists in the metabolic acidosis phase of intoxication is brought about by respiratory center stimulation by an acid pH.

Metabolic Effects

A common observation in all cases of salicylate intoxication is a significant rise in oxygen consumption. A two-fold increase in O_2 consumption has been recorded in some cases.[10] The increased O_2 requirement has been found to be independent of central and peripheral nervous control. The use of epinephrine antagonists does not affect the metabolic response; decapitated animals show an increased metabolic response. It is thought that the site of the metabolic activity is in the skeletal muscles.[10] Salicylates apparently are able to stimulate cellular metabolism directly. The net result of this increased metabolic activity is cellular hypoxia, despite hyperpnea and increased cardiac output. The hyperpyrexia, seen in salicylate intoxication, is believed to be secondary to increased metabolic activity.[4]

Acid-Base Disturbance

The usual acid-base disturbance in salicylate intoxication is initially respiratory alkalosis followed by metabolic acidosis. The respiratory alkalosis is secondary to increased pulmonary loss of CO_2 due to hyperventilation with subsequent decrease in blood CO_2.[4] Associated with the alkalosis is the development of hypokalemia. Robin and co-workers[11] reported four cases of salicylate intoxication with respiratory alkalosis and hypokalemia, and EKG changes consistent with hypokalemia. With the administration of potassium the EKG returned to normal. Neuromuscular disturbances were also observed which disappeared when potassium was given. In their cases, Robin and co-workers failed to see the development of metabolic acidosis in patients receiving adequate potassium therapy.

Some believe that acidosis in salicylate intoxication is due to a ketosis, which occurs as a result of poisoning of the Krebs cycle. Alpha-Keto-glutaric dehydrogenase and succinic dehydrogenases are apparently inhibited, blocking the conversion of alpha-ketoglutarate to succinate and from succinate to fumarate. These blockades then allow keto acids to accumulate, resulting in acidosis which inhibits the renal excretion of salicylates.[4]

Eichenholz and co-workers report that the acidosis of salicylate intoxication is due to the progressive bicarbonate deficit associated with an increase of lactic and pyruvic acid.[12] Mechanical hyperventilation without salicylate intoxication is also capable of producing metabolic acidosis with a rise in serum lactic and pyruvic acid. Experiments on fully anesthetized dogs with complete muscular relaxation showed that during the course of hyperventilation, bicarbonate fell and lactic and pyruvic acid levels rose, unless 4% CO_2 was present in the inspired air. Dogs who received 4% CO_2 in the inspired air showed no drop in serum bicarbonate and no rise in the lactic and pyruvic acid levels, and did not develop metabolic acidosis. From their studies, Eichenholz and co-workers concluded that a significant correlation existed between the fall in serum bicarbonate and the rise in blood lactate and pyruvate levels. Thus, it appears that metabolic acidosis in salicylate intoxication is due mainly to the accumulation of pyruvic and lactic acids. The mechanism by which reduced PCO_2 is able to cause a rise in pyruvic and lactic acid levels is not known.

The acidosis of salicylate intoxication has also been attributed to renal failure with accumulation of sulfate and phosphates. However, this is considered to be an uncommon and late manifestation of salicylate intoxication.[14]

Other Manifestations

Nausea and vomiting have been commonly observed in salicylate intoxication. Both central nervous system stimulation and local gastric irritation have been thought to be factors. It has been shown that administration of salicylates intravenously causes nausea and vomiting without the presence of salicylates in the gastric fluid.[15] Other experiments have indicated that nausea and vomiting occur at lower plasma levels when salicylates are given orally, than when administered intravenously.[13]

Gastric

Gastrointestinal hemorrhaging has also been noted in patients with salicylate intoxication. Epithelial desquamation and focal necrosis of the gastric mucosa are believed to contribute to the bleeding.[16] Studies by Winkelman and Summerskill showed that salicylates have no effect on the secretion of HC by the stomach.[17] They also demonstrated that acid and pepsin secretion was not affected by the administration of intravenous salicylate.

Continued

Nervous System

Salicylates in large doses have produced a marked depression of the central nervous system after an initial stimulation. Manifestations such as disorientation, stupor, hyperactivity, convulsions, circulatory collapse, coma and respiratory failure have been recorded.[14]

Leukocytes

Leukocytosis ranging from 11,000 to 20,000 per cu. mm. have been reported. Leukocytosis was found in the more seriously intoxicated patients. However, there was no correlation between the serum salicylate level and leukocytosis.[14]

Kidneys

A nephrotoxic effect of salicylates has also been reported by Lawdor and co-workers. Acute renal failure, characterized by oliguria, hyperkalemia and azotemia followed by a diuretic phase, was observed in a patient with salicylate intoxication.[18] Scott and co-workers did experiments which showed that salicylates caused a shedding of cells from the renal tubular epithelium.[19] However, they concluded that there was no evidence of nephrotoxicity with chronic salicylate ingestion.

Hypoprothrombinemia has frequently been observed in patients with salicylate intoxication. Some consider the action of salicylate to be identical with that of dicumarol. Dicoumarin is also thought to break down into salicylic acid in the body. The prothrombinopenia in salicylate intoxication can be prevented by Vitamin K administration.[14]

Hypouricemia is another common occurrence in salicylate intoxication.[11] It is thought that salicylates inhibit the tubular reabsorption of urates. Another explanation may be that high salicylate levels inhibit the activity of the enzyme uricase used in the determination of uric acid. In cases where the diagnosis of salicylate intoxication is difficult to make, hypouricemia may be an aid in diagnosis.

Adrenals

The development of Cushing's syndrome has been reported secondary to the chronic use of salicylates. It has been noted that the salicylate radical is capable of depleting the ascorbic acid content of the adrenal gland. This response can be abolished by hypophysectomy and inhibited by adrenal cortical hormones.[21]

Lungs

Pulmonary edema secondary to salicylate intoxication has been recorded. In most cases, heart disease was also present. However, Granville and coworkers report a case in which pulmonary edema developed without evidence of congestive heart failure or heart disease.[22]

Pancreas

Hyperglycemia and glycosuria occur in salicylate intoxication, making the differentiation between diabetic acidosis and salicylate intoxication difficult.[23] Salicylates are capable of causing glycosuria and hyperglycemia in nondiabetic subjects. In diabetic patients, however, large doses of salicylates have been reported to decrease blood sugar; in the late 19th century, salicylates were used to treat diabetes. The explanation of this paradoxical action of salicylates is not known. Benedict's reagent, used in glucose measurements, is reduced by salicylates as well as glucose. A positive acetone test can also occur, since the ferric chloride diacetic test measures both salicylates and diacetic acid.

Brain

Brain damage secondary to salicylate intoxication has been reported.[24] Vascular and ganglion cell changes have been observed. Vascular changes included venous engorgement with perivascular hemorrhages extending beyond the perivascular space, and dilated and congested capillaries.

Treatment

As with other types of acute intoxication, the basic treatment is directed toward rapid removal and enhanced excretion of the causative agent. However, in salicylate intoxication, the acid-base disturbances must also be managed.

Gastric Lavage

Any unabsorbed salicylate should be removed from the gastrointestinal tract. Gastric lavage and the induction of emesis should be instituted immediately.

Shock

If shock is present, whole blood, albumin or plasma transfusions should be started. Albumin is able to combine with the salicylate, making it less toxic.[14]

Hemorrhage should be treated by blood transfusion and vitamin K.[14]

Eichenholz and co-workers consider barbiturates the drug of choice in combating hyperventilation.[12] Rappoport and Guest, however, believe that barbiturate and salicylate are synergistic in their toxic and depressant action on the central nervous system, and advise against their use.[25]

Fluids

Parenteral fluids containing sodium, potassium and glucose are essential. With large amounts of fluid, urinary excretion of salicylates is enhanced. The use of sodium bicarbonate has been advocated by some but large doses may produce reappearance of respiratory alkalosis.[14] In a study by Whitten, Kesaree and Goodwin, a 50% reduction in salicylate levels within two to five hours was reported, when sodium bicarbonate was given intravenously.[26]

The use of the carbonic anhydrase inhibitor, acetazolomide was shown by Feuerstein et al.[27] to be more effective in reducing blood salicylate levels than fluids alone.

Drugs

Israels and Davies have advocated the use of trihydroxymethylamino methane (THAM) in cases of salicylate intoxication.[23] THAM is an alkaline buffer amine capable of accepting hydrogen ions. This compound in-

Continued

creases urinary pH and causes diuresis of an alkaline urine, leading to excretion of weak acids like salicylates.

Additional therapy of salicylate intoxication includes exchange transfusions, peritoneal lavage and hemodialysis. James et al. carried out experiments comparing the above three methods.[29] With exchange transfusions, they found that at least two blood volumes had to be exchanged, making the procedure long and tedious. Sensitization reactions and hypocalcemia frequently occurred. Hemodialysis was found to be the most effective method of removing salicylates. Fifty per cent of the initial dose was removed within a four-hour period. Peritoneal lavage was the simplest method; however, the rate of salicylate removal was much slower with only 25% of the initial dose removed in four hours. The best dialysate solution was one which contained 5% albumin and 10% glucose. It was noted that during the period of treatment, the amount of salicylate excreted in urine often exceeded that removed by peritoneal dialysis or exchange transfusion. This, however, did not occur with hemodialysis.

Case Reports

Case 1

This patient, a 39-year-old white woman with past history of psychoneurotic behavior, child neglect and barbiturate intoxication on an accidental basis, was admitted to Mt. Sinai Hospital on September 28, 1964. Two days prior to admission, she had been seen in the Outpatient Department with the chief complaint of severe headache, insomnia and weakness. On September 28, she was admitted with the diagnosis of hysteria and hyperventilation syndrome. On September 29, she appeared somnolent and toxic without objective neurological signs. A spinal tap was done and cerebrospinal fluid found to be normal. Blood salicylate level was obtained seventeen hours after admission, during which time she had received no salicylates, and was reported to be 39 mg.%. Blood barbiturate level was 0. Skull X rays were negative. That evening her blood CO_2 content was 18 meq/l and a second blood salicylate lovel was 33 mg.%. Urine pH was 6, and arterial blood pH was 7.51. She was given 2000 ml. 5% glucose in water intravenously during the night, and all medications were stopped. The next morning she was more alert and without symptoms.

Subsequent pertinent laboratory data is summarized below:

September 29, 1964 — Salicylate, 39 mg.% and 33 mg.% (17 and 21 hours after admission respectively)
Hb, 14 gm.%, CO_2 18 meq/l
WBC, 11,500

September 30, 1964 — BUN 13 mg.%
Glucose 130 mg.%
Cl 104 meq/l
Na+ 140 meq/l
K+ 3.2 meq/l
Salicylate 12 mg.% (34 hours after admission)
Bb 0.3 mg.%
Thymol turbidity 2, Ceph. Floc. negative
BSP 1%
Alk p'tase. 9 K.A. units
Urine pH 5

The patient was asymptomatic during the remaining five days of hospitalization and was discharged on October 5, 1964. The half-life of salicylate excretion based on above values was approximately 11 hours, consistent with an extrapolated serum salicylate level of 125 mg.% on admission.

Case 2

This patient, a 43-year-old white woman, was admitted to Mt. Sinai Hospital on November 6, 1964, with a diagnosis of hyperventilation syndrome, beginning two days prior to admission. There was no history of cough, chest pain or upper respiratory symptoms. She had had chronic recurrent headaches and nervousness for many years and frequently used aspirin preparations to relieve her headaches.

Physical examination on admission revealed an apathetic woman with shallow, rapid respirations. Nose, throat and lungs were normal. The remainder of the physical and neurological examination was entirely negative.

Laboratory studies on admission included hemoglobin of 13.8 gm.%, leukocyte count of 7,200 and a negative chest X ray and electrocardiogram. On the day after admission, blood CO_2 content was reported to be 12 meq/l, serum potassium 2.8 meq/l, and fasting blood sugar 80 mg.%. A serum salicylate level, determined 30 hours after admission, was 24 mg.%, and venous blood pH 7.45.

The patient became asymptomatic and her respirations normal during the 12 days of hospitalization, without treatment. On the basis of the low blood CO_2 content, low serum potassium, elevated venous pH and serum salicylate of 24 mg.%, 30 hours after admission, associated with hyperventilation, a diagnosis of salicylate intoxication was made. Assuming a salicylate excretion half-time of 20 hours, the extrapolated serum salicylate level on admission would have been 70 mg.%.

Because this patient had received 100 mg. sparine intramuscularly 40 minutes prior to drawing blood for salicylate measurement, the possibility that sparine might be measured as salicylate was investigated. It was found that sparine does give a color reaction, but on a mg. for mg. basis the color is only 10 to 16% as intense as that produced by salicylate. Another patient, who had not received salicylates, was given 100 mg. sparine intramuscularly and measurable salicylate levels were not observed. In order to give a false serum salicylate level of 25 mg.%, the serum sparine level would have to be greater than 100 mg.%, a level unlikely even with the largest therapeutic dosage.

Both Cases 1 and 2 presented with a history of neurotic complaints and chronic headache. In neither patient was the diagnosis of salicylate intoxication considered on admission to the hospital. Patients presenting with this type of history associated with hyperventilation must be suspected of salicylate intoxication and the serum salicylate level measured. Frequently the patient taking large quantities of aspirin for headache minimizes the amount and does not give this information unless asked.

Abstracts, Briefs and Commentaries

POSTOPERATIVE PANCREATITIS

The authors have reveiewed a series of 52 patients who developed pancreatitis following surgery at the New York Hospital-Cornell Medical Center during the years 1939-1960. Their purpose is to emphasize that this is not too rare a complication, as well as to study the clinical features and assess factors that contribute to fatality.

Forty of the patients had preceding intra-abdominal operations, seven had procedures on the urinary tract, and the remaining five had procedures unrelated to the peritoneal cavity. The most common sites of initial operation were the stomach, biliary tract and the pancreas itself.

Clinical observations of these patients suggested the need to consider pancreatitis in a postoperative patient with pain out of proportion to the procedure, fever, and ileus. Tachycardia and abdominal mass were also frequently noted.

Many patients were reoperated under the impression that some other acute abdominal problem was present. The serum amylase will be a most helpful test in the differential diagnosis.

There were twenty-seven patients who survived the episode of pancreatitis. Six patients developed pseudocysts. Twenty-five patients died of postoperative pancreatitis. In review of autopsy findings it was felt that additional surgery might have benefited six of them. Five of the patients had prominent contributory causes to their death (superior mesenteric artery thrombosis, E-Coli septicemia, pyelonephritis, metastatic carcinoma of the parathyroid, peritonitis from colon perforation and abdominal carcinomatosis). Eleven of the expiring patients had evidence of hepatic dysfunction and nine had evidence of renal disease.

The authors conclude that the mortality rate is increased with the hemorrhagic form of pancreatitis and also in the presence of renal or hepatic dysfunction.

They believe that improvement in mortality rates may result from earlier diagnosis with prompt attention to fluid and nutritional requirements, and correction of complications amendable to surgery.

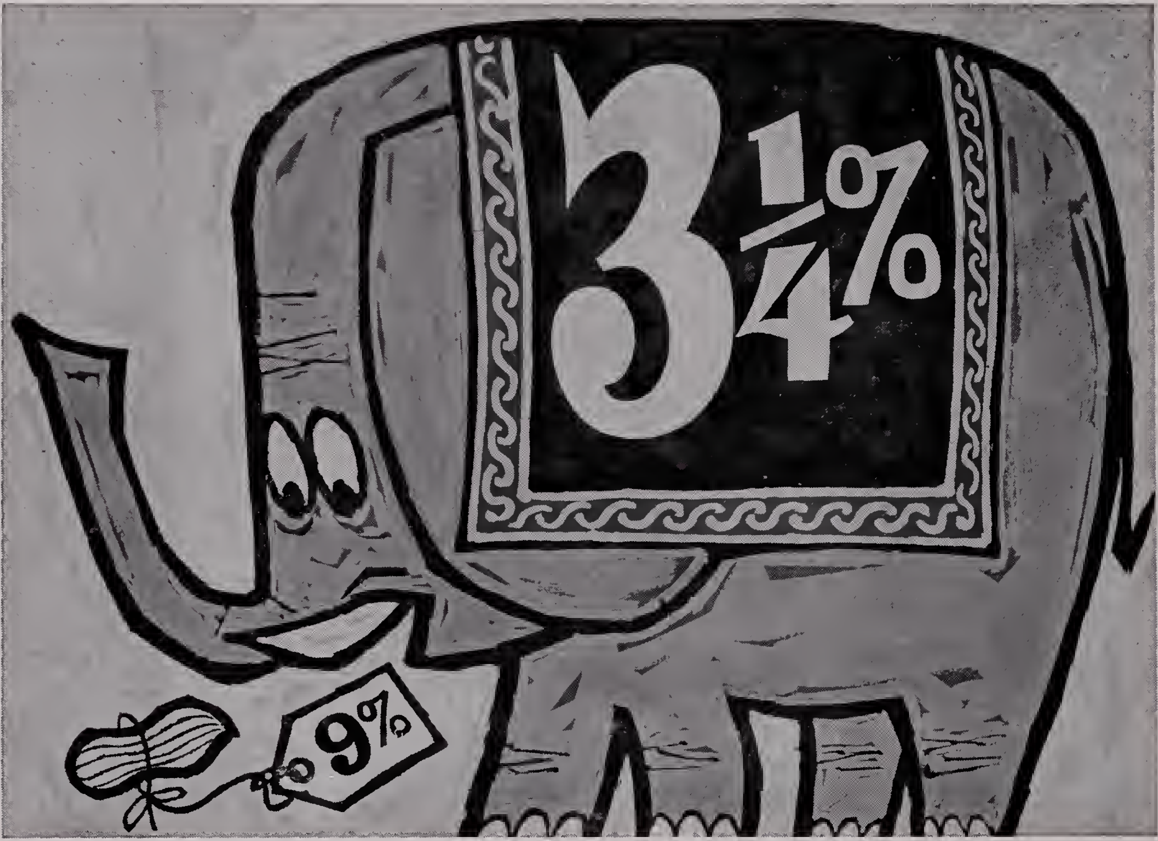
Riddle:
When is 3¼% larger than 9%?



Answer! When it represents *keepable* income from tax-free municipal bonds! A 9% yield from ordinary stocks may seem like a nice profit. But, it's really small peanuts, if you're in a high income bracket. Reason? Federal and state income taxes can take a huge amount of that profit away. Not so with *tax-free* municipal bonds! They allow you more "keepable" income . . . more big peanuts to salt away in your trunk! First National Bank offers a large selection of these bonds. Sound good? Then mail the coupon below for our free booklet "The Story Behind Municipal Bonds," as well as our handy "Tax Exempt Versus Taxable Income Table." Both give you vital information that can save you money. Or call our Investment Department (221-9463). So make like an elephant—don't forget—tax-free bonds can give you more *keepable* income!

PERIPHERAL ANGIOGRAPHY CLINICAL EVALUATION

The author believes that no one should be operated on for claudication unless he has been observed for at least a six-month period, as there are often spontaneous regressions. If there is, however, evidence of deterioration, then, of course, selective studies and necessary surgery should be carried out. In the University of Manchester, Department of Vascular Surgery, lumbar sympathectomy is used frequently and with good results, not for claudication but rather to prevent deterioration of the circulation to the foot and the skin. The author has never seen a case of "paradoxic gangrene" in approximately 1500 cases of lumbar sympathectomy and believes that this is not related per se to the procedure, but to vascular pathology in the opposite extremity.

The aortogram in *occlusive vascular disease* is of limited value and should be applied only in those cases in which there is doubt as to the diagnosis or where its use will either save the patient an operation or help define the need for surgical procedure. If there is evidence of an abdominal aneurysm over 7.5 cm. in diameter, rupture may occur and therefore this type should be resected. The author prefers the translumbar percutaneous approach for aortography but also uses the retrograde Seldinger technique.

In the femoral popliteal segment it is most important to combine the clinical examination, oscillometry, and judgment as to the need for angiography. At the time of operation the femoral popliteal segment should not only be explored, but injection of contrast below the block in the popliteal artery may be desirable to note the "run-off" of the distal arteries.

The author concludes by elucidating the two main principles in the surgical treatment of arterial disease: 1, Never run major risk to life and limb to cure minor symptoms, and 2, the feasibility of an operation is not necessarily an indication for it.

CATHETERIZATION AND PERINEAL SHAVES

A familiar practice in almost every gynecologic service is the preoperative ritual of the perineal shave and bladder catheterization. Sweeney reports a study of 424 patients to determine whether these rites are necessary and harmless.

On admission to hospital each patient scheduled for curettage or completion of an incomplete abortion was labeled at random with a red or yellow card. The patients with a yellow card received a perineal shave whereas those with a red card did not.

The decision for catheterization was left to the operator. When this was performed the urine was collected and the amount recorded. It was less than 100 ml. in 70 percent of cases. Two methods of evaluation led to the conclusion that this amount does not interfere with the accuracy of pelvic examination under anesthesia.

Of the 424 patients 97 were admitted for completion of abortion and

Continued

327 for curettage. No patient with fever or other preoperative evidence of uterine or urinary tract infection was included.

The perineal shave was done by the nurses. The patient was anesthetized, the area was gently scrubbed with a skin cleanser containing hexachlorophene and was shaved with a sterile razor. Catheterization was done under anesthesia by the house officer; the introitus and urethral meatus were sprayed with a 10 percent povidone-iodine solution and a sterile glass catheter was passed.

There were no complications among 147 patients neither shaved nor catheterized, nor among 72 who were shaved but not catheterized. Four of the 67 patients who were catheterized but not shaved had postoperative urinary tract infections, and 7 of 138 who were both shaved and catheterized had similar complications. Postoperative catheter specimens showed pyuria in all 11 patients; *Aerobacter aerogenes* was cultured from all.

The results suggest the time-honored routine of catheterization before some gynecologic operations is unnecessary and potentially harmful. Also, for routine minor operations, such as curettage and completion of incomplete abortion, the perineal shave could well be eliminated. It was found to be unrelated to the subsequent absence or development of urinary, skin or pelvic infection.

Sweeney, W.: Obstet Gynec 21:3, 291.

ELIMINATION OF ROUTINE USE OF GASTRIC DECOMPRESSION FOLLOWING OPERATION FOR GASTRODUODENAL ULCER

During a 20-month period 130 patients were operated upon for ulcer disease, including vagotomy and either antrectomy or pyloroplasty. This group was then compared with a previous group of 130 patients in whom suction had been routinely employed. However, in 20 per cent of the group undergoing vagotomy operative findings dictated the use of suction; in the resection group, on the other hand, suction was employed in 11 per cent of the elective cases and in 70 per cent of the emergency cases. It is recommended that with any development of distention suction be instituted immediately.

The major conclusion of the study was to suggest that suction should not be employed routinely, but that definite indications, such as bleeding, emergency procedure, air swallowing, etc. should be considered as proper indications for its use.

There is no question of a trend toward less use of routine suction. However, this study is obviously highly selective when emergency cases and other problem cases are placed in the suction group, and the fact that these patients have fewer complications and slightly shorter hospital stays must be carefully assessed.

RENAL CARCINOMA

Recently it has been shown that many cases of renal carcinoma are not diagnosed. Many without hematuria have nonurologic symptoms, such as fever, loss of weight, and fatigue. Because of the presence of unusual symptoms, or the absence of symptoms, renal tumors are missed.

The authors of this report made a study of 4,563 autopsies in which renal carcinomas were found. Of these, carcinoma of the kidney was the primary cause of death in 42. Twelve were undiagnosed at the time of death— 29 percent. Forty-seven were incidental autopsy findings, termed "accidental," making a total of 59 (66 per cent) not diagnosed before death.

Renal carcinoma was found in two per cent of all autopsies in this series. Of these tumors termed accidental, 26 were in men and 21 in women.

In those in which renal carcinoma was the cause of death, 27 were men and 15 were women. The average age of patients with "accidental" findings was 74 years, while the average age of the group in which death was due to carcinoma was 67.

Renal carcinomas "accidentally" found varied in size from a pea to a large orange. All tumors in this study were confirmed as carcinoma by microscopic examination.

The findings in this report are based on the records from S:t Görans Hospital in Stockholm.

It would seem unusual that so many "accidental" diagnoses should occur. The writers in a review of the literature report spontaneous regression of the primary tumor and disappearance of metastases after removal of the renal carcinoma. In our own experience kidney tumors have usually been seen by us after the mass has become large and easily palpable. Some were too fixed for removal. One patient with a very large mass survived several years after nephrectomy. The authors reviewed current literature and quoted Dr. E. T. Bell.

INTRAPERITONEAL DRAIN

From the Long Island Jewish Hospital in New York, Berliner et al. have carried out an interesting animal experiment to evaluate the use of drains from the site of an anastomosis.

As early as the turn of the century, Nikulicz doubted the value of intraperitoneal drainage and John L. Yates concluded that the peritoneal exudate from a drain is caused by its own foreign body reactions, and further stated that intraperitoneal drainage serves only the purpose of providing a path of least resistance under proper hydrostatic conditions.

Formerly it was more or less standard practice to introduce intraperitoneal drainage in colon surgery, but modern studies indicate that a drain may be harmful in that it prevents the sealing of an anastomotic leak by interposing itself between the suture line and the adjacent omentum.

Berliner, Stanley D., Burson, Leonard C., and Lear, Philip E.: Use and Abuse of Intraperitoneal Drains in Colon. Surgery 89:686, 1964.

HEMATOGENOUS METASTASES

A tumor suspension of VX-2 carcinoma of rabbits was inoculated into the thoracic aorta.

In the first experiment the spleen and perisplenic tissues were damaged by retrograde injection of nitrogen mustard into an isolated gastric branch of the splenic artery. Inoculations of tumor were made on varying days thereafter. It was found that splenic metastases were more frequent and more numerous to the extent of twenty-fold. Sixty-seven per cent of the test animals developed metastases to the damaged spleen and perisplenic tissues, compared to eight per cent in the controls. The greatest enhancement of this metastatic growth was seen between the second and fifth days after injury. This susceptibility continued to a slight degree for as long as one month after injury to the spleen.

The second experiment involved making abdominal wounds followed by an intra-aortic inoculation tumor. Some twenty times the expected inoculations or take-incidence occurred one week after injury to the abdominal wall.

The third experiment involved the effect of ischemic injury upon the formation of hematogenous metastases. This was a study of spleens damaged by ligation of the gastrosplenic vessels. Some 47 per cent of this group developed metastases to the gastric wall, a site that was assumed to have chronic ischemia by ligation of the gastrosplenic vessels. By comparison, only 5.2 per cent developed gastric metastases when these vessels were not ligated, but observed as part of another experiment where tumor cells had been injected.

In another study of the effect of wound closure with iodized catgut and wound metastases, no differences were found.

The effect of low molecular weight dextran upon the development of metastases was studied on the thesis that there might possibly be less adherence of tumor emboli through the small vessel walls. No aid was obtained.

The authors feel that they have adequately demonstrated the increased susceptibility of damaged tissue to implantation of circulating tumor cells, and since some of the method of damage was employment of nitrogen mustard infusions, caution is suggested when regional profusion techniques are to be employed in the treatment of cancer.

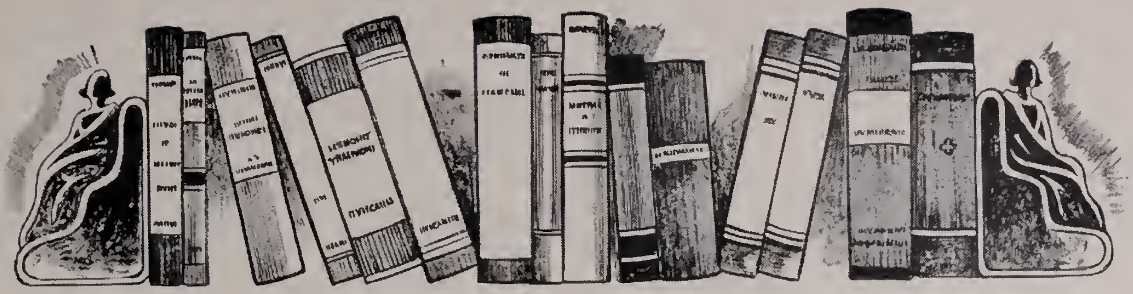
— John Barrymore



Book Reviews

A human being is not, in any proper sense, a human being till he is educated.
— H. Mann

PEDIATRIC OPHTHALMOLOGY — **L. Byerly Holt, M.D., Lea & Febiger, 1964. 403 pages. $12.00.**

This book is intended to supply the pediatrician with a reference source for eye problems. Thirty-two contributing authors have provided 37 chapters on various aspects. Some of the material is excellent, but it seems a shame that the volume is so poorly organized, proofread, and edited. The sensitive reader may be annoyed by reading identical descriptions of the same disease twice in one chapter, or by being confronted with a chapter one page long. A second edition would be welcome, but until then the pediatric student may have to wade through the present one for lack of any better comprehensive book on the subject.

William S. McClanahan, M.D.
Minneapolis, Minnesota

X-RAY TECHNOLOGY — **Jacobi and Paris, Third Edition, C. V. Mosby Company.**

This edition is essentially the same as the second edition with the exception of updated illustrations and slight text revision.

Illustrations in general are too small and could be improved by better visualization of the central ray in two projections in those examinations which require such positioning. Multiple positions of a single part should not be included on the same page.

It is noted that some basic positioning variations are not given and that in most cases, Bucky and non-Bucky technique choices are not given. In regard to techniques, only variable tissue thickness techniques are mentioned with no listing of optimum or high KV techniques, except in a few isolated examples.

Photographic illustrations of anatomical models should be replaced with clear medical illustrations, as photographs of anatomical models do not reproduce well.

The absence of such technical factors as grid ratios employed leave a technical void.

There is a noticeable absence of detailed reference to the Mathematics of exposure, regarding the variables of MAS, time, KVP and distance.

This text is recommended for student technician training programs, but quick reference for working technicians is difficult, due to the inclusion of interesting but unnecessary information.

Eugene F. Inett, R.T.
Chief X-ray Technician
North Memorial Hospital

MEDICAL PHARMACOLOGY — **Andres Goth, C. V. Mosby Company, St. Louis, Missouri. 1964; 585 pages.**

While this book cannot serve as a reference text, it is a concise, well organized presentation of pharmacology as it relates to clinical practice.

The author has constructed the book so that one can abstract an outline from it, place any basic drug in that outline and have the site of action, mode of action and basic side effects immediately defined.

The book is divided into sections on central nervous system, cardiac, gastrointestinal, chemotherapeutic and metabolic drugs. Each of these sections is prefaced with some historical background and a discussion of the physiologic prospectus of the system that can be altered or enhanced with drugs. Following then, are a small profile of each basic drug and its mode of action on the physiologic mechanism.

The book is definitely constructed with the clinician in mind. It attempts to familiarize him with expected side reactions and actions of drugs he uses daily and gives him an idea of what to expect from so-called "new" drugs. With this knowledge, he will also be able to use drugs as tests of function of physiologic systems.

Screening Preschool Children for Hearing Loss

EVELYN E. HARTMAN, M.D.*
Minneapolis, Minnesota

In a previous paper[1] preschool health-screening in Minneapolis' well-child clinics in 1961 was described. Prior to school entrance, preschool children attending well-child clinics of the Minneapolis Health Department receive a medical examination including a tuberculin test, followed at a later date by vision and hearing screening by nonmedical personnel, and laboratory tests for hemoglobin determination and urinalysis. Children who fail the vision and hearing screening are referred for further medical evaluation and treatment. A statement is requested from the hospital clinic or physician who sees the patient upon referral regarding treatment.

Prior to 1963 hearing screening was done with the Pure Tone Audiometer. It was not felt, however, that this was an ideal or completely reliable method of testing the hearing of young preschool children, although quite satisfactory for school-age children. It was hoped that a more objective method would become available.

Since January 1963, a Verbal Auditory method of screening the hearing of preschool children has been used in[1] the Minneapolis Health Department well-child clinics.[2] The method is one that had been devised for the Preschool Medical Survey of Vision and Hearing[3] sponsored by the Minnesota State Medical Association. The test is administered with the child seated before a picture board of 12 colored pictures, including such objects as a fire engine, a wrist watch, a bathtub, a snowman, a high chair and a sail boat. The child wears earphones connected with a magnetic tape audiometer. The male voice in the prerecorded and calibrated tape recording, starting at a volume of 51 decibels and decreasing by predetermined steps to 15 decibels, instructs the child to point to the various pictures. Each ear is tested separately. The monitor sits behind the child and hears the instructions

---

*Director of Maternal and Child Health, Minneapolis Health Department.

Continued

through her own earphones; she can see whether or not the child points to the correct picture. The equipment permits two children to be tested at a time.

Prior to the screening the procedure is explained to the child in a simple manner and he is asked to identify the various objects. The names of pictures causing the most difficulty are "wrist watch" ("clock" to some children) and "bathtub" ("sink" to some children). The child is considered as failing the test if he does not respond to two of the three instructions at 15 decibels with each ear. If he fails the test and no other audio problems have been noted, a second screening is done at a later date, after which if he fails again he is referred to the physician.

This paper will compare results of hearing screening in Minneapolis Health Department well-child clinics in 1961 and 1962, when the Pure Tone Audiometer was used, with results obtained in 1963 when Verbal Auditory Screening was done with a magnetic tape audiometer.

Findings

Pure Tone Audiometer Screening Method

In 1961, 351 children (172 boys and 179 girls) completed their audiometric screening. Six other children were too immature or unco-operative to be tested. Another child who failed the tests had an upper respiratory infection when tested and was to be retested in school.

Of the 351 children, 335 passed the sweepcheck screening and another nine, who had failed the sweepcheck screening, passed the threshold testing. Seven children (2 per cent) failed the threshold test in one or both ears, or had hearing problems. A child was considered failing if he did not hear sounds at 20 decibels at two or more frequencies. Of the seven cases, four were previously known and included chronic otitis media, acute otitis media, frequent upper respiratory infections with hearing loss and frequent upper respiratory infections with earache. Of the seven children, two had tonsillectomy and four received other medical care.

In 1962,[4] hearing screening was completed for 377 children. Of these, 356 passed the sweepcheck screening and 10 the threshold test. Eleven children failed the test or had other ear problems; of these, four were previously known. Four other children could not be tested. Four children had tonsillectomy; four received other medical treatment. Of the latter, one child was admitted to a speech and hearing clinic and another needed special classroom seating. No treatment was necessary for two children.

Verbal Auditory Screening Method

In 1963, 248 boys and 228 girls "graduated" from Minneapolis Health Department well-child clinics prior to entering school in September and were referred for vision and hearing screening and laboratory tests at the Public Health Center.

Four hundred twenty-six children (219 boys and 207 girls) completed their hearing screening or had previously known ear problems; they are included in this report. Three other children were too unco-operative to be tested. Another eight failed the first test and did not return for rescreening.

TABLE I

Preschool Hearing Screening

	1961				1962		1963			
			Total		Total				Total	
Screened	M.	F.	No.	Per Cent	No.	Per Cent	M.	F.	No.	Per Cent
Passed Hearing Test (No Other Symptoms)	168	176	344	98.0	366	97.1	191	187	378	88.7
Failed Test or Had Other Ear Problems	4	3	7	2.0	11	2.9	28	20	48	11.3
TOTAL SCREENED	172	179	351	100	377	100	219	207	426	100

Of the 426 children, 337 passed the first hearing test and 41 who had failed the first test passed the second screening test. Forty-eight children (11.3 per cent) failed two tests or had previously known audio problems, nine of which were previously known. Of the 48 children who failed the test or had previously known problems, 38 followed through on their medical referral. For six of these (15.8 per cent of those completing the referral) no treatment was necessary. Diagnosed medical conditions included serous otitis media, impacted cerumen in ear canals, acute otitis media, congestion in Eustachian tubes, enlarged adenoids and tonsils. One child had severe hayfever with nasal discharge, watery eyes and head congestion. Three children had previously been known to have almost complete bilateral deafness and had been under special care. One of the three had developed normally, saying words at one year of age, but after an infection at 14 months of age her speech development had stopped.

Tonsillectomy was performed for nine children, and 23 children received medical treatment or were under continuing observation. Special education classes were necessary for the three children who had bilateral deafness, and special classroom seating was recommended for three children with hearing loss in one ear.

Discussion

Comparable groups of children between four and five years of age attending Minneapolis Health Department well-child clinics were screened for their hearing. Two per cent failed the hearing screening in 1961, 2.9 per cent in 1962, and 11.3 per cent in 1963. In 1961 and 1962, of the 18 children who failed the screening, eight had previously known problems. Two children (12.5 per cent of the 16 following through on their medical referral) needed no treatment. In 1963, nine had previously known audio problems. An additional 39 failed the screening tests. Six children who were referred for medical evaluation needed no treatment (15.8 per cent of the 38 children who followed through on the referral). In 1961 and 1962 there were thus six newly identified cases needing and receiving medical treatment, found through the hearing screening program with a yield of 0.8 per cent (among 728 screened), compared with 23 newly identified cases in 1963 (out of 426 screened) with a yield of 5.4 per cent. Although our figures are too small to make definite conclusions, we believe that 30 or 40 children needing treatment were missed by the method used for screening in 1961 and 1962.

Summary

Because of its objectivity and its higher yield of auditory deficiencies the verbal auditory screening method is recommended for screening the hearing of young preschool children by nonmedical personnel. In order to avoid unnecessary medical referrals it is recommended that a retest be done for a child failing the first screening.

TABLE 2
Follow-up of Those Completing Referral for Medical Evaluation

	1961			1962			1963		
	M.	F.	Total	M.	F.	Total	M.	F.	Total
No Treatment Indicated				1	1	2	5	1	6
Tonsillectomy	1	1	2	3	1	4	5	4	9
Medical Care	3	1	4	3	1	4	12	11	23

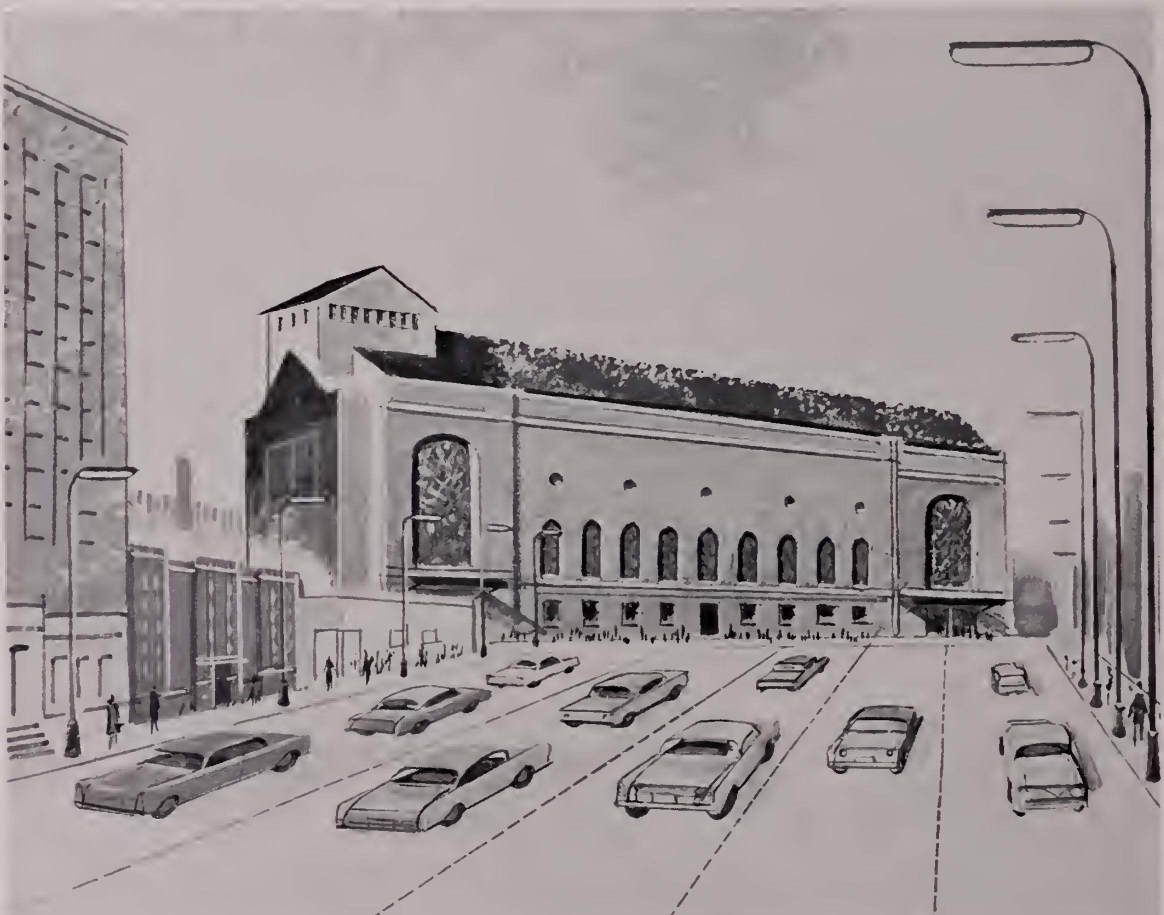
In Minneapolis . . .

WHERE MINNESOTA DOCTORS WILL BE IN '65



All roads lead to the auditorium!

112th Annual Meeting of the Minnesota State Medical Association

"The Doctor In Court," "The Need for the Medicine and Religion Dialogues," "Fractures In Children," "Relevance of the Spread of Cancer Cells to Chemotherapy" are among the topics of current medical interest scheduled for presentation at the 112th Annual Meeting of the Minnesota State Medical Association, May 17 and 18 in Minneapolis.

Scientific sessions and exhibits for a streamlined two-day meeting will be held in the Minneapolis Municipal Auditorium.

The House of Delegates will convene Sunday, May 16, at 2:00 P.M. at the Capp Towers Motor Hotel, 1313 Nicollet Avenue. The second session will convene Tuesday morning, May 18, at 9:00 A.M.

Four and one half hours Category I credit have been approved for members of the Minnesota Academy of General Practice for each of the two-day scientific sessions.

The opening scientific session, scheduled for Monday, May 17, at 9:00 A.M., will be devoted to a panel on the use of anticoagulants. Participating doctors at the opening session and their presentations are: "Indications and Contraindications" — John A. Spittell, Jr., Rochester, Moderator; "Laboratory Control of Anticoagulant Therapy" — C. A. Owen, Jr., Rochester; "Anticoagulant Therapy in Cardiac Disease" — M. W. Anderson, Rochester; "Anticoagulant Therapy in Cerebrovascular Disease" — R. G. Siekert, Rochester.

Because of the increased awareness of the need to create an interest and desire on the part of the physicians and the clergy to develop a common constructive approach in the care of the whole patient, the Committee on Scientific Assembly has arranged for a one-hour program on "Medicine and Religion" at 11:00 A.M. on Monday. Participants of both the panel and a medicine and religion round table luncheon will be Rev. Doctor Paul B. McCleave, Director, Department of Medicine and Religion, American Medical Association, and Dr. Orville S. Walters, Chairman of the Department of Student Health at the University of Illinois in Champaign.

"Fractures in Children" will be discussed by Doctor Albert B. Ferguson, Jr., Director, Children's Hospital, Orthopedic Department, University of Pillsbury, Pittsburgh, Pennsylvania, 2:00 P.M., at the opening afternoon session on Monday.

At 2:30 P.M., Doctor R. Gordon Bell, Executive Director, The Donwood Foundation, Ontario, Canada, will discuss "Alcoholism — Clinical Orientation to Addiction."

Doctor Leonard L. Lovshin, an internist from Cleveland, Ohio, will present the paper "How To Recognize Functional Disease" at the closing 4:00 session on Monday.

The scientific session for Tuesday, May 18, will constitute the Minnesota State Medical Association's observance of the 75th Anniversary of the University of Minnesota Medical School. Speakers for the Tuesday sessions will be members of the medical school faculty and alumni of world wide renown.

Doctor Raymond D. Pruitt, Professor and Chairman, Department of Medicine, Baylor University, Houston, Texas, will discuss "Cardiac Arrhythmias," at the opening Tuesday session at 9:00 A.M.

At 9:30 A.M. Doctor Claude R. Hitchcock, Minneapolis, is scheduled to present a paper on "Hyperbaric Oxygenation." A panel on "Relevance of the Spread of Cancer Cells to Chemotherapy" at 11:00 A.M. will include the following doctors: George E. Moore, Director, Roswell Park Memorial Institute, Buffalo, New York; B. J. Kennedy, J. B. Aust, and William Krivit, all of Minneapolis.

Tuesday afternoon scientific sessions will begin at 2:00 P.M. with a presentation by Doctor Jack V. Wallinga, Minneapolis. The title of Doctor Wallinga's presentation will be "Recognition of the Abnormal School Child."

The Honorable Warren E. Burger, Judge

Continued

of the United States Court of Appeals for the District of Columbia, Washington, D. C., will speak at 2:30 P.M. on "The Doctor In Court." At 3:30 P.M. Doctor W. B. Stromme, Minneapolis, will speak on "The Incompetent Cervix." A panel on the positive pap smear will climax the two-day program of scientific sessions. Panelists will include Doctors M. B. Dockerty, Rochester, Moderator; David C. Dahlin, Rochester; K. A. Prem, Minneapolis; and George J. D'Angio, also of Minneapolis.

Round table luncheons scheduled for Monday noon are: "What I Expect of the Physician in His Care of My Parishioners" and "What I Expect of the Clergyman in His Ministration to My Patients"; "Problem X-rays Related to Children's Skeletal Trauma"; "Drugs Affecting Human Behavior"; "Treatment of Burns" and "Treatment of Migraine."

The Tuesday schedule of Round Table luncheons includes the following subjects: "Current Electrocardiographic Concepts and Problems"; "Simultaneous Examination of Subject by Medical Experts before Testifying"; "Relevance of the Spread of Cancer Cells to Chemotherapy"; "Current Status of Medical Education"; "Socio-Economic Implications of Transplantations"; and "Counselling Parents of the Mentally Retarded."

American Medical Association President, Doctor Donovan F. Ward, will be the speaker Monday evening at the annual Minnesota Academy of General Practice banquet.

Following the Minnesota Academy of General Practice banquet, at 9:00 P.M. the Minnesota Chapter of the American College of Chest Physicians and the Minnesota State Medical Association will sponsor one of their Annual Fireside Conferences.

The Minnesota State Medical Association Annual Banquet scheduled for Tuesday, May 18, at 7:00 P.M. will climax the 112th Annual Meeting events.

The Third Duplicate Bridge Tournament to be held in conjunction with the Annual Meeting has been scheduled for Monday, May 17, at 9:00 P.M. The tournament is open to all players. Duplicate experience is not necessary. This will be a non-master point game. Trophies will be given for first and second place winners.

A number of the special events and social activities require advance registration. Physicians wishing to attend these events are requested to make arrangements in advance.

Many of the scientific and non-scientific committees have planned breakfast meetings in conjunction with our meeting. Kindly check the official annual meeting program for the date, time and place for your committee meeting.

William Beaumont
(1785-1853)

New occasions teach new duties; Time makes ancient
good uncouth;
They must upward still, and onward, who would keep
abreast of Truth . . .
The Present Crisis
James Russell Lowell

We know from history that great crises produce great men. In William Beaumont we have not only a great American surgeon, but also the first great American physiologist. He was born in the little colony of Lebanon, Connecticut, a farming community, which was just recovering from the Revolution. He grew up in this homespun environment, receiving a common-school education. In 1806, he left the family farm; ". . . setting out with a horse and cutter, a barrel of cider, and $100, he drove northward. . . Arriving at Champlain, New York, near the Canadian border, he was favorably impressed with the place, applied for and received the position of village schoolmaster, and taught there for three years. During these years, he decided to study medicine. He crossed Lake Champlain to St. Albans, Vermont, and became an apprentice and student of medicine under Dr. Benjamin Chandler. He remained with his preceptor for two years, preparing drugs, sweeping out the office, and assisting the doctor in his practice."[1]

A letter to his parents shows the knowledge and experience he was gaining there: "My situation affords me a very pleasant life, though it requires my utmost diligence and perseverance in the pursuit of a medical profession by which I hope to exhibit proficiency in an art which, in this enlightened age of reason and under the modern improvements of Chemistry and Physiology, bids fair to rise with healing on her wings."

Upon completing his apprenticeship, he was granted a license by the Third Medical Society of the State of Vermont, on June 2, 1812. When the War of 1812 began he joined the Army as Surgeon's mate in the Sixth Regiment Infantry. Beaumont's war diary yields some fascinating reading. "He describes 'the Surgeons wading in blood, cutting off arms, legs, and trepanning heads' after the Battle of Little York and notes, 'I cut and slashed for 48 hours without food or sleep.' He saw much fever in the army and criticizes one regimental surgeon who gave emetics and purges followed by tonics and lost 26 out of 400, while the next regiment with a diametrically opposite treatment lost no cases out of 600. He adds, 'No! depletion by blood-letting and antimonal sudorifices and diaphoretics, and an entire disuse of all tonic medicines, is the proper plan of cure.' Obviously, young Beaumont was a disciple of Benjamin Rush."[2]

In 1820 he was stationed at Fort Mackinac as post surgeon. The headquarters of the American Fur Company were there, which brought traders, rough voyageurs, and Indians to the village in large numbers. A peculiar accident in 1822, which will live on throughout medical history, took place in the crowded Fur Company store. A gun was accidentally discharged.

For complete information, write Apache Corporation, Real Estate Division, 1800 Foshay Tower, Minneapolis, Minn. 55402, or telephone 339-7781.

The whole discharge, wadding and all, entered the body of Alexis St. Martin, a Canadian voyageur about 19 years old. He fell with a cavity in the left abdominothoracic region as large as a man's palm and an opening into the stomach cavity large enough to admit a forefinger. "Dr. Beaumont was immediately summoned and, after extracting some of the shot along with pieces of clothing, and after dressing the wound, left with the remark, 'The man cannot live 36 hours.' "[3] Beaumont's surgery was effective, and St. Martin, displaying remarkable vitality, began to mend. "Genuinely touched by the youth's misfortune, Beaumont took him into his family, nursed him, fed him, and clothed him—a real act of charity since Beaumont's salary at this time was only $40 a month with two to four rations daily, out of which he had to supply his own needs, those of Alexis and support his own family as well. Alexis recovered completely in two years, but the large fistula into his stomach remained."[4] He became the object of curiosity as the man with a lid on his stomach.

Before long Beaumont conceived the idea of using St. Martin as the subject of some physiological studies. Working at the Michigan frontier, with only the crudest experimental equipment available, he laid the foundation of our knowledge of the physiology of digestion.

(To be continued in May issue)

History of Medicine in Wright County*

Theodore F. Stark, was listed in Hasty as early as 1896 and may have stayed there until about 1898. Hasty is a small inland town, or group of houses, about five miles northwest of Monticello. He graduated from Jefferson Medical College, Philadelphia, in 1877 and was licensed in Minnesota December 31, 1883. He was in Big Lake, Sherburne County in 1896 for a short time.** From 1890 on he resided intermittently in Minneapolis where he is listed as late as 1905. No further information about him could be found.

Simon Peter Starritt, apparently practiced in Monticello for a while before moving to Anoka in 1880 or 1881. He was born in Hopewell, N. B. October 9, 1847 and came to Monticello with his parents in 1856 at the age of nine years. Between 1862 and 1865 he served in Hatch's battalion in the Indian campaign. Dr. Starritt graduated from the University of Minnesota in 1875 and from Hahnemann Medical College in 1878. About 1880, as mentioned, he moved to Anoka where he died two years later, January 3, 1883.†

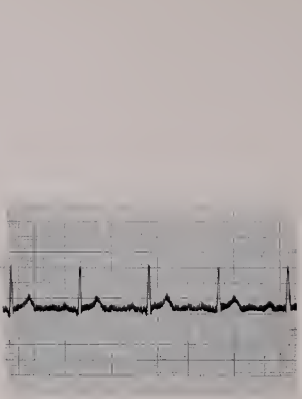
Life's perhaps the only riddle that we shrink from giving up. — William Gilbert

AC can cause ECG problems



the 500 VISO minimizes AC interference

To help you get *clear,* diagnostically *useful* cardiograms quickly and easily, special circuits in the new 500 VISO effectively cancel the most commonly occurring types of "AC artifacts." And an important companion development which takes advantage of the characteristics of the "500" is Redux *Creme* — easier to apply than an abrasive paste, aesthetically more pleasing to patient and technician alike, less time-consuming from start to finish.

This slim, lightweight cardiograph has two chart speeds, three recording sensitivities, functionally-grouped controls, interior space for all accessories, and other physiologic recording capabilities as well — yet costs only $695 delivered, Continental U. S. Call Sanborn now for full 500 VISO information. Sanborn Company, Waltham, Massachusetts 02154.

Woman's Auxiliary

43rd Annual Meeting Plans Announced

All doctors' wives are cordially invited to attend the 43rd Annual Meeting of the Woman's Auxiliary to the Minnesota State Medical Association on May 17 and 18 in Minneapolis.

The Auxiliary meeting, held concurrently with the Association's 112th Annual Meeting, promises to be an especially interesting and exciting one. Members of the Hennepin County Medical Auxiliary, under the direction of their president, Mrs. T. B. Merner, will be hostesses for the event. Mrs. Richard C. Horns and Mrs. F. G. Gunlaugson, general chairmen, have announced plans for two busy days of activity, balancing business and pleasure with the opportunity to meet new and old auxiliary friends.

On Monday morning, May 17, auxiliary members may register from 9-10:00 A.M. at either the Curtis Hotel or the Minneapolis Auditorium. At 10:30 that morning the Executive Board Meeting will be held at the Curtis Hotel, followed at 1:00 P.M. by the Executive Board Luncheon, also at the Curtis. Monday afternoon at 3:00 P.M. the Auxiliary's Annual Tea will be held in the attractive Lutheran Brotherhood Building at 7th Street and 2nd Avenue, only two short blocks from Minneapolis' major stores. Registration facilities will be provided at the Lutheran Brotherhood Building for members unable to register earlier.

Monday evening at 9:00 auxiliary members will join with members of the Association for a Bridge Tournament at the Capp Towers Motor Hotel, headquarters for the Association's meeting. The Capp Towers, at 13th and Nicollet, is a short distance from the Auditorium, and is one of Minneapolis' most luxurious new hotels, featuring exquisite decor, sumptuous food, large indoor swimming facilities, and a unique glass-domed cocktail lounge which overlooks the lights of the city.

On Tuesday, May 18, the auxiliary's Annual Meeting will be held at 9:15 A.M. at the Minikahda Country Club on Excelsior Boulevard near Lake Calhoun. For members in need of transportation, rides will be furnished from downtown Minneapolis, beginning at 8:45 A.M. At 1:00 that afternoon, the Annual Luncheon will be held at the Minikahda Club. Mrs. William H. Evans, National Auxiliary President, will be honored guest and speaker.

That evening, the meeting will end with the Annual Banquet for doctors and their wives at the Capp Towers.

All doctors' wives, whether auxiliary members or not, are urged to attend this meeting, which promises to be stimulating, interesting, and fun-filled.

Remember — the Hennepin County Auxiliary wants you in Minneapolis on the 17th and 18th of May — so mark your calendar!

How Is Your Estate Planned?

Although a great deal has been written on the subject of estate planning, it is one that is often neglected. Proper estate planning often achieves thousands of dollars of estate-tax savings.

The marital deduction is the first step in a workable estate plan. Several years ago, provisions were established making it possible to reduce extra estate taxes substantially through the proper qualification of assets. These provisions grant a deduction from the gross estate equal to the value of property passing to the decedent's spouse outright, with full power of appointment, up to a limit of 50 per cent of the value of the estate.

By taking advantage of this deduction, one can add considerably to the share of a large estate that will actually become available to the beneficiary, and can effect substantial savings even on small estates.

For example, if Doctor Smith has assets valued at $120,000, use of the marital deduction could save $9,340 for his wife in the event of his death:

	Marital Deduction Not Used	Marital Deduction Used
Gross Estate	$120,000	$120,000
Specific Exemption	60,000	60,000
Net Estate	$ 60,000	$ 60,000
Marital Deduction (50 per cent of gross estate)	———	60,000
Subject to Tax	$ 60,000	None
Federal Estate Tax	9,340	None

Beware of the tax trap on large estates. Many men leave their entire estates to their wives, and if the gross value is in excess of $120,000 they incur tax losses. Remember that the marital deduction is limited to 50 per cent of the value of the estate. If you leave your wife a greater share, the property in excess of 50 per cent will be taxed in your estate, and will be taxed a second time in her estate if it has not been exhausted during her lifetime.

A way of avoiding this trap is to leave one's wife one-half the estate outright, to qualify for the maximum marital deduction, and then place the other half in a trust so designed as to give her all the benefits of the income and principal, but to avoid incurring taxes in her estate. Under such a trust, she can receive all income during her lifetime and can be paid sums from the principal for purposes stipulated in the trust agreement.

The remainder of the trust, upon her death, will pass untaxed to the beneficiaries originally named in her husband's will (usually the children). On a $200,000 estate, the tax pictures would be as follows:

	100% to Wife	50% to Wife 50% to Trust
Gross Estate	$200,000	$200,000
Specific Exemption	60,000	60,000
Net Estate	$140,000	$140,000
Marital Deduction	100,000	100,000
Doctor's Taxable Estate	$ 40,000	$ 40,000
Federal Estate Tax	$ 4,800	$ 4,800
Wife's gross estate, provided that she has lived on the income and has retained the entire principal.	$195,200	$100,000
Specific Exemption	60,000	60,000
Wife's Taxable Estate	$135,200	$ 40,000
Estate Tax	$ 31,000	$ 4,800
Tax Savings through Use of Trust		$ 26,200

Obviously, proper planning of your estate can thus mean many additional thousands of dollars for your family. You can see that technical errors could be quite costly. Thus, it is advisable for you to consult your attorney for help in setting up your program.

Most of us don't mind doing what we ought to do when it doesn't interfere with our doing what we want to do. — Cincinnati Inquirer

FREO, BY SAUNDERS SCHULTZ

FREE YOUR PATIENTS from
√ deficient neutralization
√ poor taste
√ burdensome cost
with DICARBOSIL® antacid

- **effective neutralizing power**—Two tablets in vitro[1], provide nearly 2 hours' relief within effective pH range 3 to 5.5.
- **pleasant taste**—A fresh mint flavor patients continue to enjoy, because with Dicarbosil's unique* formulation, chalky aftertaste is no longer a problem.
- **exceptional economy**—Due to its high neutralization capacity combined with low cost (1¢ or less per tablet), Dicarbosil is within the reach of all patients.

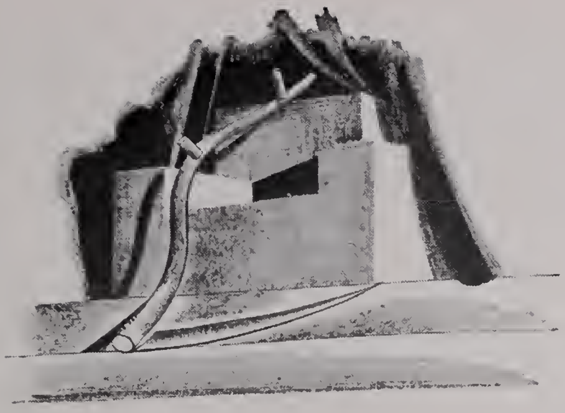
RELIGION IN AMERICAN LIFE



In Memoriam

A good man, when dying, once said, "Formerly death appeared to me like a wide river, but now it has dwindled to a little rill; and my comforts, which were as the rill, have become the broad and deep river."

We call it death to leave this world but were we once out of it and instated into the happiness of the next, we should think it were dying indeed to come back to it again.
— Sherlock

FRED W. WITTICH

Dr. Fred W. Wittich, 80, St. Louis Park physician, died February 4th. He was born in Carlysle, Pa., and was a graduate of Johns Hopkins University School of Medicine.

Dr. Wittich was the founder and first president of the International Association of Allergology and a former secretary-treasurer of the American College of Allergists. He was a fellow of the American College of Allergists, American Academy of Allergy, editor of the Review of Allergy and Applied Immunology, former faculty member of the University of Minnesota extension division and associated with the Glen Lake Sanatorium and Hennepin County General Hospital. He was a member of the Hennepin County Medical Society and American Medical Association and a life and 50 Club member of the Minnesota State Medical Association.

He is survived by his wife and two sons.

ALBERT E. OLSON

Dr. A. E. Olson, 69, prominent Duluth surgeon and a former University of Minnesota regent, died February 17th, unexpectedly in his home. He was born at Duluth and received his medical degree from the University of Illinois.

Dr. Olson served on the staffs of both St. Luke's and St. Mary's hospitals, was a life member of the American College of Surgeons, and a member of the St. Louis Medical Society, Minnesota State Medical Association and the American Medical Association.

He is survived by his wife and two sons.

MERCHISLAW M. SARNECKI

Dr. M. M. Saarnecki, 56, St. Paul surgeon, died February 10th. He was born at Cleveland, Ohio, and received his degree in medicine at Northwestern University Medical School.

He was on the staff at Ancker, Bethesda and St. John's hospitals, and was a member of the Ramsey County Medical Society, Minnesota State Medical Association and the American Medical Association.

He is survived by his wife and children.

Physician's Diary

> *Thou mayest be sure that he that will in private tell thee of thy faults, is thy friend, for he adventures thy dislike, and doth hazard thy hatred; there are few men that can endure it, every man for the most part delighting in self-praise, which is one of the most universal follies that bewitcheth mankind.*
>
> *— Sir Walter Raleigh*

Dr. W. A. Brand, 89-year-old Redwood Falls practicing physician, was named "outstanding senior citizen" of Redwood county by the board of commissioners in January. **Dr. P. L. Halenbeck** of St. Cloud was named Stearns county's "outstanding senior citizen" by the senior citizens council, and **Dr. F. E. Ellison** of Howard Lake was named Wright county's "outstanding senior citizen." These gentlemen will compete against entries from all counties in the state to name the State of Minnesota's "outstanding senior citizen."

* * *

Drs. Kurt Pollak, Henry L. Williams of Minneapolis and **Dr. Clifford F. Lake** of Rochester will be part of the instructional staff for the introductory course in "Expanded Surgery of the Nasal Septum" to be presented at the Methodist Hospital Graduate Medical Center, Indianapolis, April 21-24.

* * *

Dr. A. Sigrid Halversen Gilbertsen of the Nicollet Clinic, Minneapolis, and **Dr. Arnold W. Fenske** of the Winona Clinic, Winona, addressed the American Association of University Women, Winona Branch, at their annual meeting in January. **Dr. Gilbertsen** spoke on "The Role of Heredity in Certain Blood Disorders," and **Dr. Fenske** spoke on "Pills and Progress."

* * *

Dr. Robert E. Peters of St. Paul was elected recently to the newly-created office of chairman of the board of directors of the Minnesota Heart Association.

Dr. D. L. Johnson of Little Falls was elected president of the St. Gabriel's hospital staff. Other officers elected were: **Dr. G. M. A. Fortier**, vice president, and **Dr. R. J. Stein** of Pierz, secretary-treasurer.

* * *

Dr. Ian Gregory, associate professor at the University of Minnesota, will become professor and chairman of the Department of Psychiatry in the Ohio State University College of Medicine, April 1st.

* * *

NEW LOCATIONS: **Dr. Richard Castillo** of Berkeley, California, has opened up a medical practice in Plainview . . . **Dr. Donald A. Bolt** of Tacoma, Washington, has opened up an office in the PBC Medical-Dental building, in Brooklyn Center . . . **Dr. Carl A. Schwartz**, formerly of Austin, now is associated with **Drs. W. S. Chalgren** and **J. B. Lund** in Mankato . . . McNear, Jr.**, at the Heron Lake Clinic . . . **Dr. Clinton C. Rhodes** has joined the staff of the Itasca Clinic in Park Rapids. **Dr. Rhodes** has been interning at Ancker hospital in St. Paul . . . **Dr. R. E. Olson** has joined the partnership of the Valley Medical Clinic with **Drs. Gerald E. Nelson** and **Dr. G. T. Schimelpfenig.**

New broad-spectrum penicillin but without broad-spectrum toxicity[1-10]

no blood dyscrasias
no photosensitivity
no severe gastric disturbances
no pigmentation of teeth
no kidney damage
no accumulation in long bones

PENBRITIN (ampicillin) brings the traditional penicillin advantages to areas of treatment formerly dominated by the tetracyclines and chloramphenicol – urinary and gastrointestinal infections, as well as respiratory infections. But PENBRITIN (ampicillin) *does not cause the toxic disorders* associated with other broad-spectrum antibiotics.[1-10] And highly important: PENBRITIN (ampicillin) *kills* bacteria instead of merely suppressing them.

Usual dosage: Adults – 250 mg. every six hours in respiratory infections; 500 mg. every six hours in urinary and gastrointestinal infections (higher doses may be needed in severe infections). Children – (under 13 years, whose weight will not result in a dosage higher than that recommended for adults) 100 mg./Kg./day in divided doses every six or eight hours for moderately severe infections; 200 mg./Kg./day in divided doses every six hours for severe infections.

Contraindications: (1) Hypersensitivity to penicillin. (2) Infections by penicillinase-producing staphylococci and other penicillinase-producing organisms.

Side Effects: Mild effects, such as skin rashes, diarrhea, nausea and vomiting have occasionally appeared.

Precautions: As with other antibiotics, precautions should be taken against gastrointestinal superinfection. To date, safety for use in pregnancy has not been established.

Supplied: No. 606 – Each capsule contains 250 mg. of ampicillin. Bottles of 16 and 100.

"All Registered Nurses are Alike"

It stands to reason. They all go through the same training; they all have to pass the same tests: they all have to measure up to the same standards. Therefore, all registered nurses are alike.

That's nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all registered nurses aren't alike, either.

SIGNEMYCIN®

Side Effects: Glossitis and allergic reactions, as well as severe anaphylactoid reactions, have been reported as rare side effects. Should significant reaction or idiosyncrasy occur, discontinue medication and institute countermeasures. Use of tetracycline during the last trimester of pregnancy, neonatal period and early childhood may cause discoloration of developing teeth. Reduce usual oral dosage and consider serum level determinations in patients with impaired renal function to prevent possible liver toxicity due to excessive accumulation of antibiotic in the serum.

Precautions: Overgrowth of nonsusceptible organisms may occur. In such cases, discontinue medication and institute appropriate specific therapy as indicated by susceptibility testing. Aluminum hydroxide gel given with antibiotics has been shown to decrease their absorption and is contraindicated. The coloring agents used in Signemycin Syrup and Pediatric Drops may produce red discoloration of stools.

Triacetyloleandomycin, a constituent of Signemycin, administered to adults in daily oral doses of 1.0 Gm. (3 Gm. Signemycin) for periods of more than ten days may produce hepatic dysfunction and jaundice. In the rare patient who requires this high dosage level of Signemycin initially, liver function should be carefully followed and dosage should be reduced, as promptly as possible, to the usual recommended range of 1.0 to 2.0 Gm. per day. Therefore, Signemycin is recommended primarily for the treatment of acute or severe infections, with treatment restricted to a ten-day period. If clinical judgment dictates continuation of therapy beyond ten days, serial monitoring of the liver profile should be carried out, including BSP, transaminase, and cephalin flocculation tests. Changes observed in liver function were reversible following discontinuation of the drug.

Formulas: Capsules: 250 mg. Signemycin (167 mg. tetracycline HCl and 83 mg. oleandomycin as triacetyloleandomycin).

Capsules: 125 mg. Signemycin (83 mg. tetracycline HCl and 42 mg. oleandomycin as triacetyloleandomycin).

Syrup: 125 mg. Signemycin (tetracycline equivalent to 83 mg. tetracycline HCl and 42 mg. oleandomycin as triacetyloleandomycin) per 5 cc.

Pediatric Drops: 100 mg. Signemycin (tetracycline equivalent to 67 mg. tetracycline HCl and 33 mg. oleandomycin as triacetyloleandomycin) per cc.

PFIZER LABORATORIES Division, Chas. Pfizer & Co., Inc. New York, New York 10017

Of 5,057 patients with confirmed infections of all body systems... 4,731 or 93.5% were treated successfully with Signemycin®

Note:

The high rate of response to Signemycin in these cases is noteworthy because the totals include many patients with difficult-to-treat infections, many whose infections had proved resistant to other agents, and many who had been treatment failures on other therapy.[1-87] In addition the following criteria were used for the cases cited: (1) only published results were used (2) results were confirmed by clinical and/or laboratory findings (3) patients were cured, not "improved" (4) dosage conformed with current recommendations in the United States (5) no other anti-infective agents were used concomitantly (6) no instance of prophylactic use was included in these tabulations.

Condition	No. of Patients	No. Responded To Signemycin
Ear, nose and throat infections	507	465
Respiratory infections	1,028	954
Gastrointestinal infections	425	387
Genitourinary infections	748	684
Skin and soft-tissue infections	1,088	1,036
Bone and joint infections	71	64
Deep-seated or generalized infections	257	251
Obstetrical & gynecological infections	341	320
Miscellaneous conditions	592	570
Totals	5,057	4,731 (93.5%)

consistently effective...often when others fail

GERIATRIC SYNDROME

vhen a change in environment overwhelms him with anxiety

ailing health, financial difficulties, or the death of a pouse are among the reasons why elderly people may e obliged to leave their familiar surroundings. Moving with children or entering a home for the aged may atisfy practical requirements but can be psychologically traumatic since emotional resilience tends to dimin- n with age.

ven when anxiety reaches overwhelming proportions, ou can counteract it promptly with the potent tranuilizer—Atarax (hydroxyzine HCl).

e outstanding systemic safety record of Atarax makes particularly suitable for geriatric patients whose drug lerance is often low. The usual initial dosage in such atients is 50 mg. q.i.d. However, this tranquilizer is so ell tolerated that dosage can be adjusted to meet invidual requirements. The wide variety of dosage rms allows flexibility of administration from any andpoint—convenience, patient preference, or emerency requirements.

No age, of course, is exempt from anxiety and any number of circumstances can unleash it. Keep Atarax in mind for *all* your emotionally distressed patients—from under 6 to over 60.

for any age—for any stage of anxiety

Rx ATARAX®
(hydroxyzine HCl) tablets syrup parenteral

...In any condition where tissue depletion of the water-soluble vitamins is found, Rx **RoeriBeC®** therapeutic B complex with 500 mg. of vitamin C.

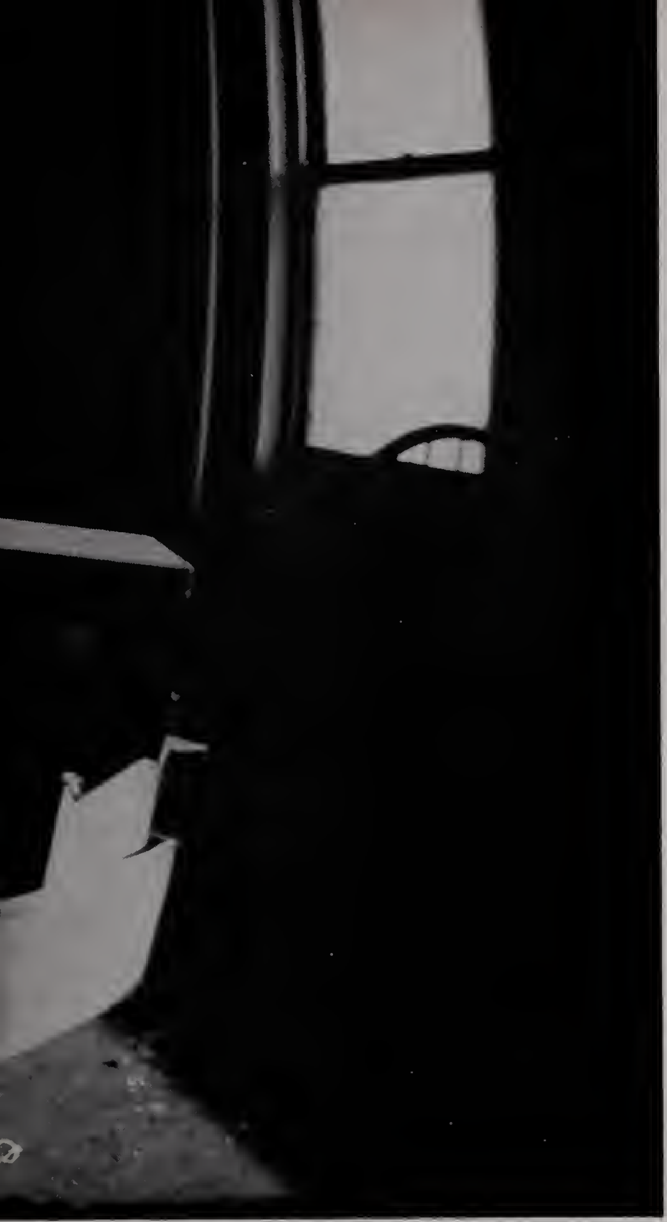
Division, Chas. Pfizer & Co., Inc.
Science for the World's Well-Being®
New York, New York 10017



Side effects and precautions: The transitory drowsiness which may occur with hydroxyzine HCl usually disappears spontaneously in a few days with continued therapy, or is correctable by dosage reduction. Dryness of the mouth may be seen with higher doses. Involuntary motor activity has been reported in hospitalized patients on higher than recommended doses. Hydroxyzine HCl may potentiate CNS depressants, narcotics such as meperidine, barbiturates, and anticoagulants. In conjunctive use, dosage for these drugs should be decreased. Because drowsiness may occur, patients should be cautioned against driving a car or operating dangerous machinery. **Parenteral Solution Precautions and contraindications:** This dosage form is intended only for I.M. or I.V. administration and should not, under any circumstances, be injected subcutaneously or intra-arterially. When the usual precautions for I.M. injection have been followed, reports of soft tissue reactions have been rare. I.V. administration should be slow, no faster than 25 mg. per minute, and should not exceed 100 mg. in any single dose. Particular care should be used to insure injection only into intact veins; a few instances of digital gangrene occurring distal to the injection site have been attributed to inadvertent intraarterial injection or periarterial extravasation, both of which should be avoided. **More detailed professional information available on request.**

nicotron™ Nicotinic Acid and Aminoacetic Acid (Glycine)

Like Radiant Sun

Warms Cold Hands and Feet

nicotron™

NICOTINIC ACID +
AMINOACETIC ACID (Glycine)

increases and sustains peripheral blood flow (1-2)

INDICATIONS: Poor circulation causing cold hands and feet or pain on walking. For the more serious peripheral vascular disturbances such as . . . Raynaud's Disease, Meniere's Syndrome, intermittent claudication, diabetes, post-phlebitis syndrome, leg ulcers due to venostasis and chronic thrombophlebitis.

DOSAGE: 1 or 2 teaspoonfuls or 1 or 2 tablets 3 times a day before meals. The feeling of warmth and tingling of the skin is a desirable effect. If this reaction is too pronounced reduce dosage.

CONTRAINDICATIONS: There are no known contraindications.

SUPPLIED: 8 oz. bottles and bottles of 100 chew-tabs.

FORMULA: Each teaspoonful (5ml.) elixir or each chew-tab contains:

Nicotinic Acid	75 mg.
Aminoacetic Acid (Glycine)	750 mg.

Why not Miltown®?

There are few "nots" in Miltown therapy

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its anti-anxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

Indications: Many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.
Precautions: Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Side Effects: Agranulocytosis, constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, impotence, leukopenia, muscle cramps, nausea, postural hypotension, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.
Average Dosage: One tablet (100 mg.) daily with breakfast.
Availability: Tablets of 100 mg. in bottles of 100 and 1000.
For full details, see the complete prescribing information.

Kapseals®
Benadryl®
(diphenhydramine hydrochloride)
PARKE-DAVIS

To Combat Symptoms of Tree-Pollen Allergy

This time-tested agent provides two actions that effectively combat symptoms of seasonal allergy: *Antihistaminic*—relieves sneezing, nasal congestion, itching, and lacrimation. *Antispasmodic*—relieves bronchial and gastrointestinal spasm. **Precautions:** Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this product. Hypnotics, sedatives, or tranquilizers, if used with BENADRYL, should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENADRYL. **Side Effects:** Side reactions, commonly associated with antihistaminic therapy and generally mild, may affect the nervous, gastrointestinal, and cardiovascular systems. Most frequent reactions are drowsiness, dizziness, dryness of the mouth, nausea, and nervousness. BENADRYL is available in several forms including Kapseals containing 50 mg.

The pink capsule with the white band is a trademark of Parke, Davis & Company. 72465

Age 12-13—not too soon to pay attention to her acne

At the first sign of acne...the first comedone or seborrhea... "this is the time to institute preventive measures—the time to try to prevent progression to pustulation and scarring."[1] Regular, frequent washing with pHisoHex, antibacterial detergent, can enhance any acne management program, help to clear acne skin faster and better.

pHisoHex is more than a superior cleanser. It contains 3 per cent hexachlorophene, an optimal amount. This powerful antibacterial agent is deposited on the skin where, as an invisible, tenacious film, it degerms between washings. Among 67 acne patients who used pHisoHex, "...results were eminently satisfactory."[2] When pHisoHex was used as the wash in another series of 42 acne patients, "no patient failed to improve."[3]

Why not recommend three or four pHisoHex washings daily and exclusively to all your acne patients? pHisoHex provides superior cleansing action and is nonalkaline, hypoallergenic and "kind" to skin. And for "...a very effective topical treatment for acne vulgaris"[4] prescribe keratolytic pHisoAc® Cream along with pHisoHex. pHisoAc Cream contains colloidal sulfur 6 per cent, resorcinol 1.5 per cent and hexachlorophene 0.3 per cent. It dries, peels and masks lesions. Of 100 patients treated with pHisoHex and pHisoAc (and a low-fat diet), 79 showed good-to-excellent improvement.[4]

pHisoHex is available in unbreakable plastic squeeze bottles of 5 oz. and 1 pint, in plastic bottles of 1 gallon. pHisoAc is supplied in tubes of 1½ oz. For complete acne therapy, prescribe or recommend the special *Combination Package* containing both pHisoHex and pHisoAc Cream.

GENERAL INFORMATION

Authors

Manuscripts for consideration in Minnesota Medicine should be addressed to Office of Publication, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Papers should be typed double spaced on white paper with a wide margin. The first page should list the title, the name of the author (or authors), degree, and any institutional or other credits. Pages should be numbered consecutively. Tables should be typed and numbered and should have a brief descriptive caption.

Bibliographical references should be limited to twelve and should be typed in conformity to the method used by the Index Medicus. They should be numbered consecutively in the order in which they first appear in the text. Book references should give the name of the author, title, edition number, publisher, and the year.

Illustrations (photographs, tables, and graphs) should be submitted on separate sheets of paper and not combined in the text. Instructions for combining photographs are acceptable.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

President's Letter

The editor informs me that if all goes well this issue of *Minnesota Medicine* will be in your hands during early May which gives me the opportunity to discuss the annual meeting of our association in Minneapolis, May 16 to 18. This meeting is always exciting, and this year's program has some features of special interest. On Sunday the sports minded gentry will have their golf and skeet shooting. For those poor souls who are condemned (with their full knowledge and consent) to the smoke-filled halls of the House of Delegates the speaker, Dr. Falls, has arranged for all of the Delegates and any other interested physicians to attend the meeting of the reference committee which will consider the report of the ad hoc committee for the study of Blue Shield. No other reference committee will meet at that time. As I mentioned last month, the activities of Blue Shield in the near future may be of great importance to all practicing physicians. The suggestions for a closer relationship between Minnesota physicians and Minnesota Blue Shield ought to be of interest to all.

This year the scientific sessions will be limited to two full days, on Monday and Tuesday. The schedule presents an enticing mixture of home state talent and authorities from afar speaking on a wide range of subjects. The Academy of General Practice has approved nine hours of credit and, in addition, offers a chance to hear our neighbor, Dr. Donovan Ward speak as the President of the American Medical Association. We are particularly proud to dedicate Tuesday's scientific program to the University of Minnesota Medical School in honor of its 75th Anniversary. The speakers on that day will be alumni or past or present members of the faculty of the University. The banquet on Tuesday evening is an event of recognition and entertainment which no one will want to miss. As usual, the Woman's Auxiliary will help our wives in becoming better informed while they enjoy themselves.

Scientific meetings of state medical societies are not all in a healthy condition. Numerous specialty programs and post-graduate courses offer significant competition. To the credit of Minnesota physicians their attendance in recent years has been respectable, but it should be better. The program committee has not yielded to suggestions that our meeting be confined to a session of the House of Delegates. The scientific and social events and the commercial exhibits will be crisp, interesting, and well worth your time. I hope to see most of you in Minneapolis to meet old friends, make new ones, and gain some new viewpoints.

security checkpoint

Even raw materials of the highest quality are not above suspicion. That's why we screen them through this "security sieve." It separates foreign elements from all incoming material intended for granulation. Here's how it works: The screen vibrates over a tub at the rate of 1,000 to 3,000 times a minute and sifts the material. Anything larger than the specified particles is left behind. The sieve is engineered by an action called "annular rotation" so that all particles will ultimately come in contact with the screen surface. Security screening is just one aspect of an elaborate program at Eli Lilly and Company to insure the highest quality in our finished products.

The Incidence and Management of Chlorpromazine

Skin-Eye Syndrome*

L. M. TREDICI, M.D.**
BURTRUM C. SCHIELE, M.D.***
W. S. MC CLANAHAN, M.D.†
Minneapolis, Minnesota

WITH THE advent of the phenothiazines in the treatment of the mentally ill, the whole outlook for the psychotic patient has radically changed. Sometimes treatment with these drugs effects prolonged remission of disturbing symptomatology so that patients may function in environments outside the hospital, and sometimes such treatment prevents the mental deterioration that requires prolonged custodial care. The phenothiazines are by no means innocuous drugs. Since their introduction many side effects have been described and studied, some of which are specific to a particular chemical group and some of which are generic to the entire phenothiazine family. Different side effects have variously interested investigators in the ten-year period that these drugs have been used to treat the emotionally ill, and measures to prevent or correct complications have been proposed and tested with varying degrees of success. However, with the use of larger doses and the growth of total length of administration, new and occasionally fatal side effects have appeared. Since very early in the tranquilizer era, those who have prescribed the phenothiazines have been aware of a transitory photosensitivity to sunlight and the subjective complaint of blurred vision in some patients receiving chlorpromazine (thorazine), but both of these side effects have been very easily corrected by discontinuing the drug. The complications recently described, however, comprise changes which do not appear until after years of treatment and seem to be permanent in character.

Review of Literature

In 1962, French investigators reported, without any discussion of possible physiopathology, a case of facial purplish pigmentation in a patient treated with large doses of chlorpromazine for a number of years.[1] At the beginning of 1964, investigators from the University of British Columbia, Canada, described skin discoloration in conjunction with ocular pigmentation in a series of 70 chronic psychiatric patients at the Provincial Mental Hospital in Essondale.[2] The one thing common to these patients was massive, long-term chlorpromazine therapy.

The skin change consists of a metallic-looking purplish-gray tinge in areas exposed to natural light, principally on the face, neck and forearms. The discoloration may be accompanied by deposits of yellowish-brown pigment in the exposed areas of the conjunctiva, cornea and the anterior central portion of the lens. The ocular deposits can be observed clearly with the slit lamp. The deposits in the skin, which occur mainly in the superficial layers of the dermis and in cells adjacent to the capillaries, can be demonstrated in microscopic sections, where they appear similar to melanin.

A further report described the occurrence of sudden and unexplained death in twelve patients thus affected. At autopsy an accumulation of similar pigment was found in the parenchymal cells of the internal organs.[3] Recently, Satanove has suggested that this complication is due to the phototoxic action of sunlight on the phenothiazine in the skin. The accumulation of melanin and chlorpromazine metabolites may be the cause of the purple color.[4]

Clinical Findings

We in Minnesota became interested in searching for similar cases and have re-

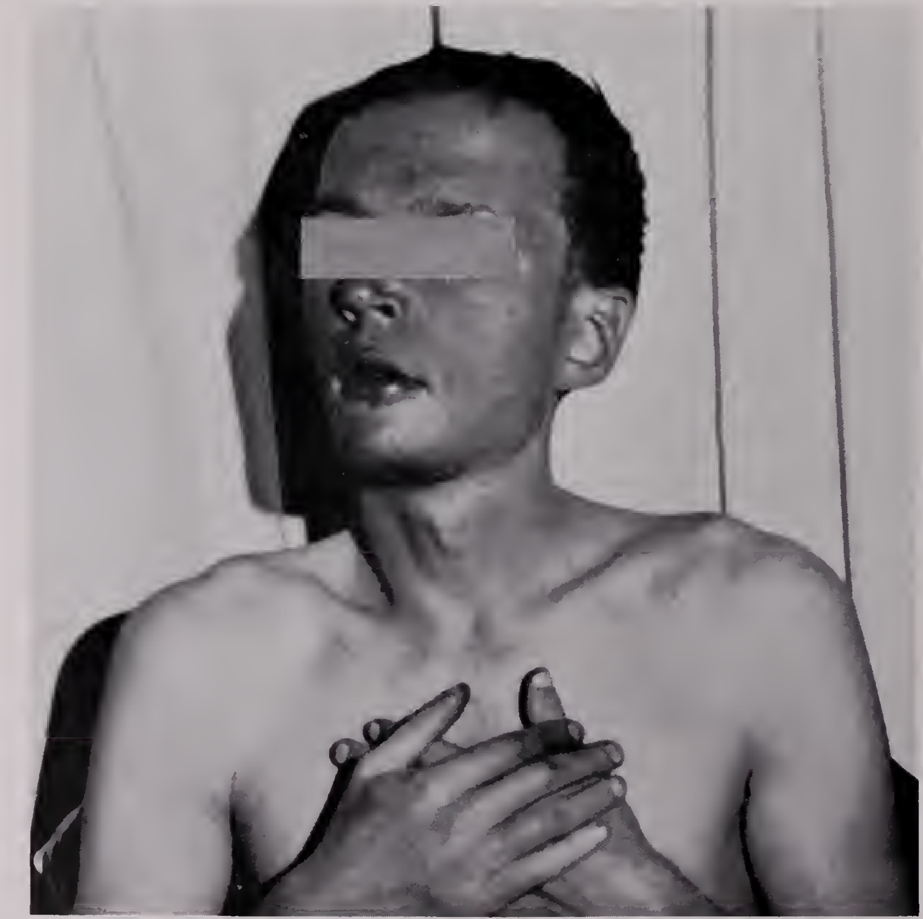

Fig. 1 — Patient 6. Note typical pigmentation on exposed portions of skin.

viewed the populations of two state institutions, where we were able to identify twelve patients who had easily detectable components of the skin-eye syndrome. The dermatologic aspects of some of the cases in our series have already been described in a previous report.[5] The number of patients in both hospitals is around 1700, the cases identified representing 0.7 per cent of the total population. Of the twelve patients (Table 1) found to be affected in our two-hospital population, nine had both eye and skin involvement, one skin involvement only, and two eye involvement only. Figure 1 illustrates a typical case. This photograph was taken in the winter. Conjunctival pigmentation in another patient is shown on the cover of this Journal. Ten patients were female and two male. Ages ranged from 22 to 55 years, and total length of hospitalization from four to 29 years. The physical health of the patients in this sample has been generally good, with the exception of one patient who had tuberculosis in 1947 (later arrested), and one who was treated for anemia in 1960. Visual acuity, where possible to test, was normal except in two patients, one with previous thioridazine-(Mellaril) induced retinopathy** and another with advanced cataract thought to be secondary to chlorpromazine administration. Funduscopic examination was in all cases normal except for the case with the retinopathy. Laboratory data on all patients were essentially normal. Psychiatrically, ten of these patients were classified as schizophrenics, one had psychosis associated with mental deficiency and one had chronic brain syndrome associated with brain trauma.

The total amount of chlorpromazine received by this group varied from 530 gm. to 1890 gm. for periods totaling from three to nine years. Only one patient received more than 1900 gm. of chlorpromazine, but because of a history of confinement at various hospitals it is impossible to state with any accuracy just how much was given; it is estimated, however, that his total dosage was between 2500 and 4000 gm. over approximately seven years of treatment. The highest daily dosage given each patient ranged from

1200 mgm. to an estimated 5000 mgm.

Searching for patients who had received a similar course of chlorpromazine medication without developing dermatologic or ocular pathology, we were able to find six in the two hospitals. All had received similar total amounts of the drug and similar large daily doses. Their cases are summarized in Table 2. We were thus able to find only eighteen patients in the current two state-hospital population of 1700 patients who had received high dosages of chorpromazine for long periods, and of these eighteen patients, twelve (66 per cent) have developed one or both components of the skin-eye syndrome.

Discussion

A thorough and satisfying explanation of the etiology of skin and eye pigmentation after prolonged administration of chlorpromazine has not yet been put forward. There is very little doubt that chlorpromazine is the drug implicated, as it has been the one consistently administered in all our cases and in those mentioned in the other reports. Although our patients received other phenothiazines, either in combination with chlorpromazine or alone, in no instance were the total amounts administered anywhere near the total amounts of chlorpromazine given, nor did any of these patients receive another drug for periods approaching the length of time they were maintained on chlorpromazine.

It is obviously impossible to predict how much chlorpromazine given for what length of time will produce skin or eye pathology in any given patient. One can only say that these complications appear when large doses are given for extended periods and that the individual patient undoubtedly constitutes the most important variable. This is easily demonstrated by a comparison of Tables 1 and 2, which show that period of administration and total amount of drug received were very similar in both groups and that some patients who developed the syndrome had even received considerably smaller quantities of the drug than some patients who, to all appearances, still have not developed skin or eye changes.

Age was not an apparent factor, as all patients in our series are young or middle-aged adults (22 to 55 years old) and therefore correspond to the age group most likely to have schizophrenia and who are most commonly treated with the phenothiazines in the largest doses for the longest periods. With respect to sex, it is at once apparent that skin and eye pigmentation tends to appear more frequently in females than in males (a ratio of six to one in this series). It is possible to theorize that there could be a deposition of pigment exclusively in internal organs in the patients listed in Table 2, but this is entirely speculative and cannot be demonstrated at the present time. Neither does the appearance of skin or eye pigmentation seem to follow any predictable time sequence. In our sample, previous dermatologic pathology was not predictive that pigment would be deposited in the skin; patients 4, 6, 8, and 12 had known dermatologic trouble in the past (acne, erythematous dermatitis, seborrheic dermatitis), and although patients 4, 6, and 8 later presented skin pigmentation, it has been impossible to demonstrate any skin involvement in patient 12 (Table 1).

Unexplainable sudden deaths among patients with skin and eye pigmentation have been mentioned. There is a similar case in our series. Patient 10 suddenly died after experiencing for 48 hours symptoms consistent with a common cold. This patient was still receiving chlorpromazine, although she had developed skin changes. There had been no noticeable changes in behavior or in mental status, and death was completely unexpected. No signs of homicide, suicide, or struggle of any nature were found. Unfortunately, we cannot give any further findings, since permission for autopsy was denied by her relatives. In the death books of both institutions, from 1960 until the present, we have not been able to find any other case of sudden death which could have been due to similar causes.

The finding of ocular pigmentation without skin involvement in two patients in this series is so far as we know unique in the literature. Since chlorpromazine was discontinued in those two patients, we cannot determine whether they would have later developed skin involvement or if at the time the drug was discontinued any of their internal organs presented pigment deposits.

Management

In all the patients listed in Table 1 (except for patient 10), chlorpromazine has been discontinued and other tranquilizers substituted. These patients have continued to follow their usual routines in the hospital. Patients 1, 2, 3, 4, 6, and 9 have not received chlorpromazine for over six months. In none of them has there been noticeable regression or increase of pigmentation or ocular pathology. Patients 5 and 8 have not taken chlorpromazine for 12 and 17 months, respectively; their conditions are also unchanged. Of the patients listed in Table 2, patients 3, 4, 5, and 6 have continued to take chlorpromazine under close supervision. Examination has as yet failed to demonstrate any pathological changes. Whether such changes will eventually develop is, of course, an open question.

When a patient has been identified as having any component of the skin-eye syndrome, chlorpromazine should be promptly discontinued. In fact, at our present state of knowledge, it might be more prudent to discontinue all psychotropic* drugs and to manage the patient in another manner if at all possible. If the patient continues to be disturbed and needs some type of psychotropic medication, we would recommend a trial with reserpine. In this series, patient 6 had been viciously assaultive for many years, and many attempts at treatment with all forms of therapy, including special management, electroshock, and various drugs, had failed to benefit him. (Note that he had received the largest total dose of chlorpromazine of any of our patients — up to 5000 mgm. a day.) All phenothiazines were discontinued in this patient in May 1964, and he was placed on reserpine in July. At present, his behavior is vastly improved.

If all other treatments fail and the patient remains a difficult management problem, cautious trials with other phenothiazines might be warranted. As yet nothing is known about the possibilities of cross sensitivity, but it seems logical that the more potent compounds of the piperazine class which do not characteristically induce skin reactions and light sensitivity might be tolerated by these patients. Drugs of this type include prochlorperazine (Compazine), trifluoperazine (Stelazine), perphenazine (Trilafon), fluphenazine (Prolixin, Permitil), thiopropazate (Dartal), acetophenazine (Tindal), and carphenazine (Proketazine). It would not seem logical to use the more sedative phenothiazines such as thioridazine (Mellaril), triflupromazine (Vesprin), and promazine (Sparine), which might not be as safe. It might also be well to have affected patients avoid excessive exposure to sunlight, particularly for the first few weeks after chlorpromazine has been discontinued.

Reduction of the abnormal skin and eye changes may become possible through the use of chelating agents. Greiner, Nicolson and Baker[6] in a preliminary report, claim that four out of six pigmented patients improved markedly following a course of treatment with D-penicillamine.

While it is apparent that chlorpromazine is the drug involved in this adverse reaction, we have no assurance that other phenothiazines might not also be capable of producing similar changes. We must keep in mind that chlorpromazine was the first drug to be introduced and has been used in excess of all the other phenothiazines combined.

Conclusion

We have reported on a new side effect of the most widely used and oldest of all the phenothiazines, chlorpromazine. This complication, because of the characteristics of its occurrence, could hardly have been noticed until a relatively short time ago. Our opinion is that the usefulness of chlorpromazine should not be greatly compromised by this new development; however, we would emphasize that closer supervision of patients who have received this agent for prolonged periods is called for, especially when the drug has been given at high doses. Chlorpromazine should always be permanently and promptly discontinued when any sign of skin or eye pigmentation appears. Temporarily withdrawing chlorpromazine for months or even years does not seem to be of any value in preventing eventual occurrence of pigmentation, as most of the patients in the present series were without chlorpromazine for longer or shorter periods in the course of therapy.

---

*See Test Your Word Score, page 627.

We feel that even a large total amount of chlorpromazine administered over a long period of time is not sufficient in itself to bring about the skin and eye changes observed, as we were able to compare our series of affected patients with a similar series of patients who had undergone equally long-term, high-dosage therapy with chlorpromazine but who did not demonstrate the same pathology. It appears that other factors, still unknown, but possibly involving differences in metabolic pathways, may be implicated in the production of these complications. With more extensive investigation of the metabolism of chlorpromazine, it may be possible to avoid producing this complication or to treat it after it has developed. For the present, however, close observation and suitable precautions should be the watchwords.

IT'S THE LAW

Hospital Liable for Pathologist's Misinterpretation of Biopsy — A hospital was held liable for a pathologist's negligent misinterpretation of biopsy material, as a result of which a patient's uterus was unnecessarily removed. The Ohio Supreme Court, in affirming lower court judgments, held that the hospital was estopped* from disclaiming responsibility, since it represented that the pathologist was in its employ as a part of its regular establishment.

The pathologist had a salary contract with the hospital to do pathological work, but he was ostensibly connected with the hospital as an employee. Bills for his services to hospital patients were rendered by the hospital, and his pathological reports were made under the name of the hospital. In the trial court, the jury found him to be an agent, by estoppel, of the hospital.

The high court also ruled that the suit was not barred by the state's one-year statute of limitations on malpractice cases. The statute does not begin to run, the court said, until a medical relationship has finally terminated. In this case, suit was filed more than a year after the patient left the hospital following a hysterectomy performed after the pathologist diagnosed her condition as carcinoma of the cervix. However, she returned to the hospital periodically for cancer checkups, and suit was filed within a year of the final checkup. Moreover, the court ruled, since a hospital may not lawfully practice medicine, the two-year statute of limitations governing ordinary negligence in personal injury cases, rather than the malpractice statute, could be applied in this case.

Multiple Basal Cell Epithelioma

• Jaw
• Cyst
• Syndrome

LYLE V. KRAGH, M.D.
JOHN K. GROTTING, M.D.
Minneapolis, Minnesota

RECENTLY A syndrome has been described in which patients have multiple basal cell epitheliomata and, in addition, cystic lesions in the upper and lower jaws.[1] The skin lesions vary from trichoepitheliomata,* or nodular basal cell lesions, to ulcerative invasive growths. The prominent feature of the skin lesions is the multiplicity of the growths (multiple epitheliomata occurring over a relatively few years) and the occurrence of these malignancies in young persons, often as early as puberty.

The epithelial cysts described are limited to the mandible and maxilla and, though often in close proximity to developing teeth, are not necessarily all dentigerous* cysts.

Other frequent features of this syndrome are bifid ribs, calcification of the dura or falx cerebri, broad nasal root, frontal bossing, spinal scoliosis and cutaneous pits on the hands and feet.[2,3]

The frequent appearance of the basal cell epitheliomata, usually on the face, is the most obvious manifestation, and the jaw lesions are often asymptomatic. In the case presented here, a young man with numerous basal cell epitheliomata of the face was subjected to roentgenographic examination of the facial bones and skull. Two large "dentigerous cysts" were present, one in the mandible and one in the maxilla.

Case Report

A 23-year-old man came under care in September, 1961. One month previously, a basal cell epithelioma had been removed from behind the right ear. At this time a two-centimeter basal cell epithelioma was present in the left eyebrow region. This was excised and the defect repaired by a local rotation skin flap.

In January, 1964, four basal cell epitheliomata (nose, forehead, right lower eyelid, and right eyebrow region) were excised and the wounds closed primarily. In August, 1964, three epitheliomata were removed from the left lower eyelid and the left lateral canthus region.

In August, 1964, roentgenograms of the facial bones, skull and chest were obtained. A large cystic lesion was present in the ascending ramus of the right mandible and another large cyst in the maxilla. Both of these cysts were in close proximity to abnormally located teeth. No spinal scoliosis was present clinically, but the forehead was prominent and the nasal root was markedly widened. Marked frontal bossing was noted on the skull roentgenogram and calcification of the falx cerebri was present. Roentgenographic examination of the chest did not reveal presence of bifid ribs.

The patient stated that his mother had had a facial epithelioma treated by radiation therapy. Because of the reports of familial occurrence of this syndrome, the patient's parents were examined.

His father, age 54, had never had any lesions removed from the facial skin and none were present at this time. There was nothing in the clinical examination to suggest frontal bossing, hypertelorism,* scoliosis, or jaw deformities.

The patient's mother, age 56, had a depressed scar on the cheek from radiation treatment of an epithelioma in 1964. Lesions which clinically appeared to be basal cell epitheliomata were present over the right lateral canthus, left upper lip, and left knee regions. Her forehead was prominent, showed marked bossing, and moderate hypertelorism

---

*See Test Your Word Score, page 627.

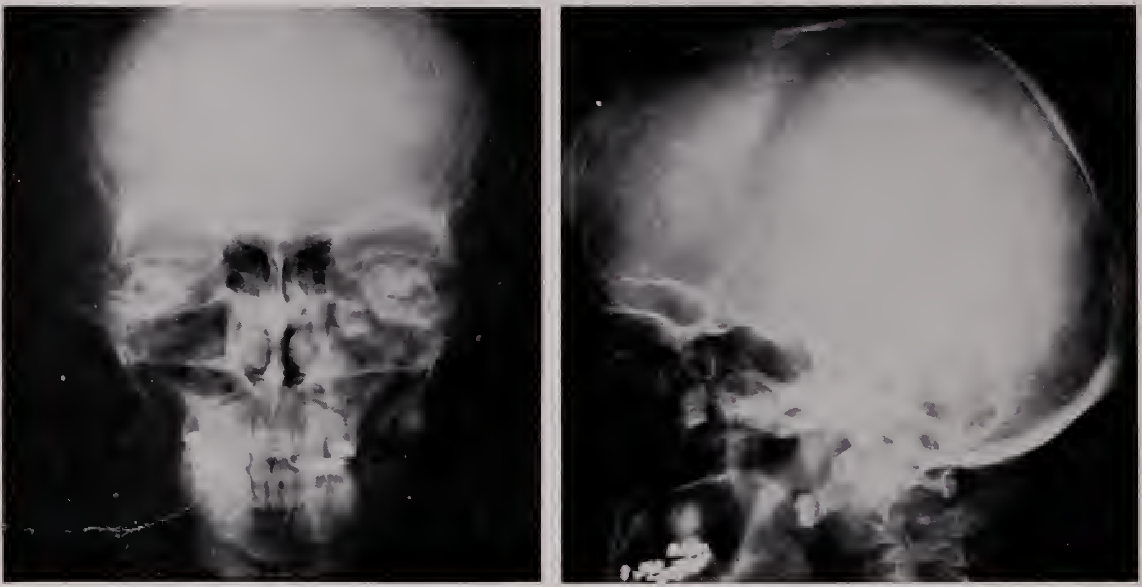

Fig. 1 — Roentgenograms of skull and facial bones showing maxillary and mandibular odontogenic cysts.

was present. No scoliosis or jaw deformities were noted on clinical examination. She gave a history of having a left mandibular jaw cyst treated by marsupialization* eight years previously.

Discussion and Summary

This case is briefly presented to call attention to a recently recognized but not uncommon clinical syndrome. A young patient who, over the past several years, has developed eight distinct basal cell epitheliomata of the facial skin, was found on roentgenographic examination of the facial bones to have two large intraosseous cysts with teeth in close association with them (Figure 1). Other skeletal abnormalities were present and are recorded above. The syndrome was probably also present in his mother.

The cystic masses in the jaws should be removed, or at least observed closely for change in their character. Should these cysts expand to where fracture is likely, or if they appear to be ameloblastomas, they should definitely be removed.

The basal cell epitheliomata of the skin (usually facial) are best managed by plastic surgical techniques. Often they can be simply excised; but occasionally, because of size or location, a free skin graft or a local rotation pedicle skin flap may be needed to repair the defect. Though irradiation therapy will control the individual lesions, it should not be employed once the syndrome is recognized, because of the relatively young age of the patients and the probability that more lesions, possibly dozens, will develop over the ensuing years. The long-term management of the repeated crops of epitheliomata about the face and body can be better handled by surgical means.

Pleural Effusion Associated with Coxsackie Disease*

WILLIAM R. FIFER, M.D.**
St. Louis Park, Minnesota
C. DWIGHT TOWNES, M.D.†
Minneapolis, Minnesota

THE FIRST clinical syndromes due to Coxsackie viruses were described by Daae and Homann in Norway in 1872,[1] and by Finsen in Iceland in 1874; but the Coxsackie viruses were not isolated until 1948.[2] Finsen called the disease "pleurodynia" because pleural pain was the outstanding feature of the syndrome he described. The first recorded outbreak of pleurodynia in the United States was in Charlottesville, Virginia, in 1888. On that occasion the term "devil's grip" was coined to describe the pleural pain.[3]

The term "Bornholm disease" (after the Danish Island in the Baltic Sea) was first used by Sylvest in his famous monograph written in 1934.[1] Other pseudonymns for epidemic pleurodynia,‡ besides "Bornholm disease" and "devil's grip," are "epidemic muscular rheumatism," "Bamle disease," "epidemic pleuritic pain," and "acute benign dry pleurisy."[4]

It was not until 1948 that Dalldorf and Sickles recovered the causative virus from the stools of two children with paralytic poliomyelitis. The specimens were collected in the village of Coxsackie, New York, on the banks of the Hudson River below Albany.[5] Like poliomyelitis and ECHO viruses, the Coxsackie group are enteroviruses. They are divided into Group A and Group B on the basis of the lesions they produce when injected into suckling mice. Group A viruses produce lesions in skeletal muscle, while viruses of Group B are principally neurotropic. They have been isolated from flies, cockroaches, and mosquitoes.[5] There are

now 24 Group A and six Group B strains available for classification, numbered B1, B2, etc.[3]

Syndromes Due to Coxsackie Viruses

Of the common syndromes, *Group A viruses* cause herpangina, and *Group B viruses* are recovered in epidemic pleurodynia, aseptic meningitis, pericarditis, and myocarditis. These commoner syndromes often coexist, overlap, and are "complicated" by other symptoms or syndromes.

Table 1 presents a list of syndromes due to Coxsackie viruses noted in a recent perusal of the literature, illustrating the diversity of clinical illnesses due to Coxsackie infection.

Because Coxsackie viruses can be recovered from healthy people at times, acceptable proof of infection due to a Coxsackie virus consists of (1) isolation of the virus from the stool or diseased tissue, and (2) demonstration of a significant rise in antibodies neutralizing the specific (group-type) strain recovered from the stool.[6]

Complications

Epidemic pleurodynia has been "complicated" by *orchitis and myocarditis* in the same patient.[2] It has also been "complicated" by *pericarditis,* and even in 1933, long before epidemic pleurodynia was identified as a Coxsackie virus infection, Bing reported six cases of pericarditis occurring in patients with Bornholm disease.[7] In epidemics of Coxsackie disease, some patients have *pleurodynia,* while others present other syndromes, such as *hepatosplenic syndrome or pneumonitis.*[3] A small summer epidemic (21 isolates in 28 cases) at Walter Reed Hospital resulted in isolation of four types (B2, B3, B4, B5) of Coxsackie B viruses in the same epidemic. The patients had various syndromes (pleurodynia with orchitis, myocarditis, neonatal encephalomyelitis, pericarditis, aseptic meningitis, etc.) as part of the same epidemic. In fact there were ten distinct syndromes in 28 cases, 15 of which were predominantly pleurodynia.[8]

Sizable epidemics of Coxsackie disease have been studied in Shreveport, Louisiana (1948), California (1956), Massachusetts (1957), Toronto (1958), Great Lakes Naval Base (1958), Montreal (1960), and Lind, Washington (1961). In Lind, 142 cases of B2 Coxsackie disease occurred among the 697 townspeople. In this epidemic, there were 22 cases of pleurodynia, seven of orchitis, and three of epididymitis.[9]

While pleural pain is common in Coxsackie infections, pneumonia and pleural effusion are rare.[10] As stated earlier, one of the pseudonyms for pleurodynia is "acute benign *dry* pleurisy," implying that pleural effusion is not seen in this disease, and study of reported outbreaks confirms the notion that pleural effusion is uncommon.

In 1961 there was an extensive outbreak of illness clinically suggesting Coxsackie disease in Nassau County (N.Y.), and the New York State Health Department isolated 84

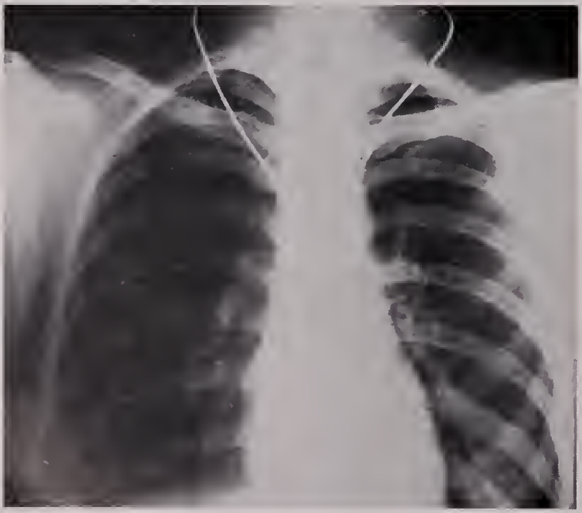

Fig. 1 — (a) PA Chest X ray 7/23/64 negative at onset of illness.

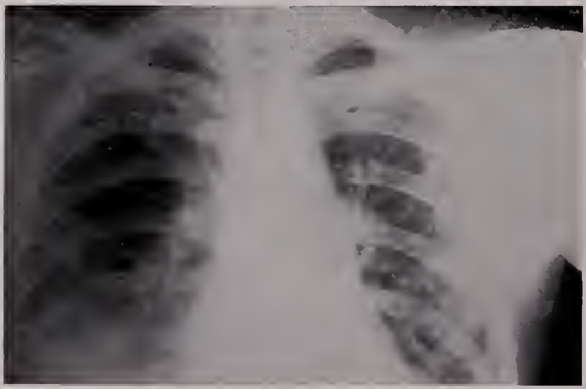

Fig. 1 — (b) PA Chest X ray 8/2/64 demonstrating parenchymal infiltration and pleural effusion at right base.

strains of Coxsackie B5 in 1961; but no cases of pleural effusion were mentioned.[11] In a large (114 cases) epidemic in Boston reported in 1949, a pleural friction rub was heard in 28 cases (25%), but all 98 chest X rays taken were normal.[4] In the Lind, Washington, epidemic of B2 Coxsackie disease, "signs of pleurisy were not found," although 22 patients had pleural pain.[9]

Only three instances of pleural effusion were discovered in an incomplete survey of the recent literature. In the large outbreak (500 cases) in Shasta County, California, in 1956,[1] three cases of pleural effusion were described, all with pericarditis. Coxsackie virus was not isolated in any of these three patients, but two had a significant antibody rise on paired blood specimens. One patient had bilateral pleural effusion, with thoracentesis yielding "275 cc. of thick red fluid."

Because of the rarity of pleural effusion due to Coxsackie disease, the following case is reported:

Case Report

A 23-year-old housewife became ill abruptly on 7/22/64 with severe pain in the epigastric area, in the lower anterior thorax bilaterally, and between the scapulae posteriorly. The chest and epigastric pain was associated with generalized myalgia and fever of 105.4°. She was hospitalized on 7/23/64 for relief of pain and was noted to be "splinting" the thorax. A chest X ray was negative (Fig. 1) and no friction rub was noted. The leukocyte count was 4200/mm.^{3} with a normal differential count. Erythrocyte sedimentation rate (ESR) was 44 mm./hr. The pain and fever relented in a few days without specific therapy, and she was discharged on 7/27/64, feeling well.

TABLE 2
Viral Studies

	7/23/64	8/7/64
Influenza A	Neg.	Neg.
Influenza B	Neg.	Neg.
Adenovirus	Neg.	Neg.
Coxsackie	1:4	1:256

The Coxsackie Serology pertains to Antibodies of B4 Variety Neutralizing the B4 Coxsackie Virus Recovered from the Patient's Stool Collected 7/27/64.

She became ill again on 7/28/64 with chills and fever to 104°, associated with severe pleuritic pain in the right anterior lower thorax. Physical examination disclosed rales and evidence of a right pleural effusion, confirmed by X ray 8/2/64 (Fig. 1). The hospital course was marked by daily fever to 103°, despite administration of penicillin and tetracycline, until 8/7/64, when the fever relented. A repeat chest X ray 8/9/64 showed increase in the right pleural effusion. Thoracentesis of 400 cc. of amber fluid was performed on 8/10/64. An intradermal tuberculin test (O. T. 1:1000) was negative. She was discharged 8/11/64 and gradually gained back weight and strength. Subsequent X rays (9/8/64) still demonstrated pleural disease, at least some of which was effusion on lateral decubitus view (Fig. 1).

Coxsackie B4 virus was isolated from the patient's stool collected on 7/27/64, and a significant rise (1:4 to 1:256) in B4 neutralizing antibodies was demonstrated (Table 2).

Repeat intradermal tests with tuberculin (O. T. 1:1000) and histoplasmin were negative 9/8/64. The following tests were also negative or normal: cold agglutinins, psittacosis complement fixation (CF) test, throat culture, pleural fluid culture, and CF tests for histoplasmosis, blastomycosis, and coccidioidomycosis.

Summary

A case of pleural effusion associated with Coxsackie disease has been reported. The

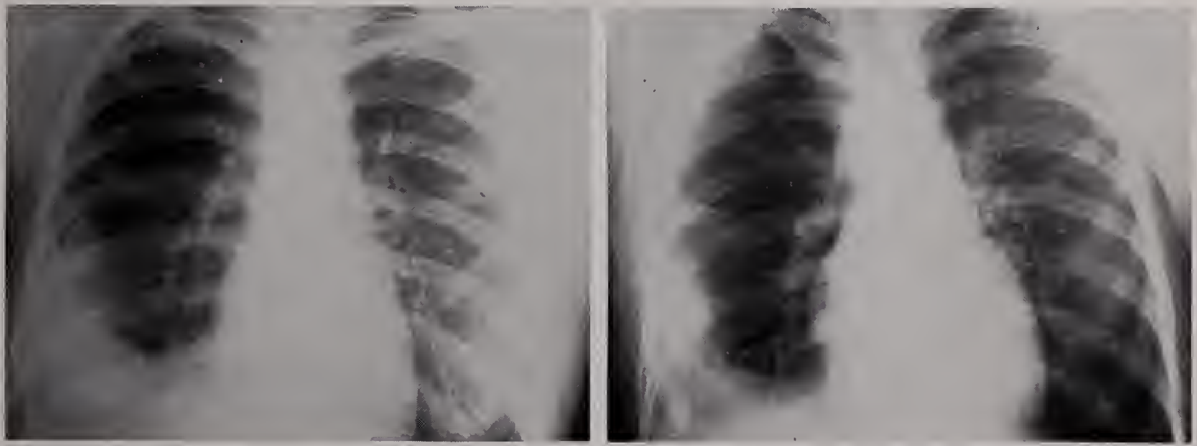

Fig. 1 — (c-left) (d-right) PA and Right Lateral Decubitus Chest X ray 9/8/64 demonstrating free pleural fluid.

Coxsackie virus, Group B, Type 4, was recovered from the stool, and a significant rise in titer of neutralizing antibodies to that virus was demonstrated in the patient's serum at a time when she had a clinical illness characterized by pleurodynia and a large pleural effusion.

A brief review of the history of diseases due to Coxsackie viruses has been included; the diversity of clinical syndromes due to infection with Coxsackie viruses has been described; and the rarity of pleural effusion associated with Coxsackie virus infection has been emphasized.

FIBRINOGEN — FIBRIN CONVERSION SYNDROME
(Abruptio Placenta Syndrome)

This clinically consists of an abnormal separation of a normally implanted placenta associated with hypofibrinogenemia, hemorrhage and shock. It may occur as often as one in two hundred fifty deliveries.

It is associated with severe abdominal pain which is caused by tetanic contraction of the uterus, and as this occurs there is marked vaginal hemorrhage from incoagulable blood. Shock may supervene.

Hypofibrinogenemia is the result of absorption into the maternal circulation of thromboplastin which causes the fibrinogen fibrin conversion syndrome. Clinical symptoms occur at a level below 150 mg./100 cc. of plasma fibrinogen and the critical level is 90 mg. per cent.

The etiology of this syndrome may be toxemia, hypertension, chronic glomerulonephritis, chronic vascular disease or trauma. It is to be differentiated from placenta praevia in which the bleeding is painless and tetanic contractions of the uterus and the fibrinogen depression are absent.

Energetic treatment is required for abruptio placenta syndrome and the intravenous administration of fibrinogen should be continued until the serum level is well above the critical point of 90 mg. per cent. If this condition is not recognized, prognosis is grave.

Primary Aldosteronism*

JAMES E. STEVENSON, M.D.**
FREDERICK M. OWENS, M.D.**
EUGENE RINKEY, M.D.**
FRANCIS B. TIFFANY, M.D.**
St. Paul, Minnesota

PRIMARY ALDOSTERONISM, a syndrome of mineralocorticoid excess, was first described by Conn.[1] The classical clinical picture is characterized by hypertension, nocturnal polyuria, intermittent or continuous weakness of skeletal muscles, headache, polydypsia, paresthesias, intermittent "paralyses," and tetany. Laboratory studies show severe hypokalemia, hypernatremia, alkalosis, hyposthenuria, and increased amounts of aldosterone in the urine. Numerous cases[2,3,4] have been described in the literature since the entity was defined. Patients with primary aldosteronism may be asymptomatic, with benign hypertension and hypokalemia being the only clinical abnormalities.

Report of a Case

In May 1963, a 38-year-old woman consulted a physician because of weakness of the legs of one year's duration. Previously the patient had enjoyed good health. The weakness of the legs was so severe that, at times, the patient was forced to crawl up the stairs. At the time of the initial physical examination the blood pressure was 170 mm. Hg systolic and 120 diastolic. An electrocardiogram and a roentgenogram of the thorax were interpreted as normal. The patient entered Miller Hospital on May 13, 1963, for further studies.

During the first hospital admission additional information was obtained from the patient. In the 12 months prior to consulting a physician, she had experienced episodes of dull, aching pain and stiffness in the lower extremities lasting up to one week. The pain was exaggerated by exertion but not by coughing, sneezing, or straining at stool. It migrated from one extremity to the other. The distress ceased during menstruation. In the course of the three months prior to the first admission, the patient had experienced pain in the upper extremities, predominantly in the forearms. During one episode, the arms could not be elevated above the head, because of the severity of the pain. A complaint of tenderness over the radial aspect of the right forearm was elicited. All examiners were impressed by the "hysterical" flavor of the complaints and the apparent indifference to the distress. The result of a Minnesota Multiphasic Personality Inventory was "psychoneurosis, conversion reaction."

No visual difficulty, loss of weight, or intolerance to heat were experienced. The past history revealed that the blood pressure five years prior to admission was 130 mm. Hg systolic and 90 diastolic. Shortly before the first admission, the systolic blood pressure was 190 mm. Hg, and the diastolic varied from 70 to 110 mm. Hg. The patient had not conceived in 20 years of marriage, allegedly because of the husband's infertility. The patient's father was first observed to be hypertensive at the age of 30 years.

Physical Findings

Physical examination revealed a healthy, middle-aged, moderately obese woman in no acute distress. The blood pressure was 160 mm. Hg systolic and 100 diastolic. Funduscopic examination demonstrated Grade I hypertensive changes. The thyroid gland was not enlarged. There was no cardiomegaly; the cardiac rhythm was regular and no murmurs were audible. Palpation of the paraspinous muscles elicited no tenderness or spasm. The cranial nerves functioned normally and the peripheral reflexes were equal bilaterally. There was no detectable muscular weakness or incoordination.

Laboratory Findings

Results of laboratory studies during the first and subsequent admissions are recorded in Tables 1 and 2. Of special interest was the low serum potassium and the low specific gravity of the urine. An intravenous pyelogram performed during the first admission was interpreted as normal.

---

*This study was supported in part by Research Training Grant 5 T1 HE-5570 and Research Grant HE-5694 of the National Heart Institute, National Institutes of Health, USPHS.

**From the Departments of Pathology, Surgery, and Medicine, The Charles T. Miller Hospital, St. Paul, Minnesota, and the Departments of Pathology and Surgery, University of Minnesota, Minneapolis, Minnesota.

Progress

During the first five days of the first admission the patient experienced increasing pain in the calves and slight ataxia. Intravenous administration of 40 mEq. of potassium chloride was followed by an increase in severity of the pain in the legs. The blood pressure remained in the range of 150 mm. Hg systolic and 90 diastolic. The patient was discharged on a program of a weight-reduction diet and orally-administered potassium chloride in doses of one gm. taken three times daily.

Further Evaluation

On June 18, 1963, the patient was admitted for the second time for further evaluation because primary aldosteronism was now suspected. During this admission, a classical history of severe muscular weakness, paresthesias, polydypsia, polyuria, nocturia and tetany was elicited. The patient had not received thiazides at any time. The blood pressure was 140 mm. Hg systolic and 100 diastolic. There was an equivocal Chvostek's sign. The results of the physical examination were otherwise unchanged from those of the initial admission.

Laboratory Data

Several interesting relationships of the laboratory data should be emphasized. The levels of serum potassium varied from 2.2 to 3.2 mEq/L, while the levels of sodium in the serum and the carbon dioxide content of the blood were in the high normal ranges. The excretion of urinary sodium when the patient was maintained on a diet containing 550 mg. of sodium was considerably below the normal of 75-200 mEq/24 hours. The urinary excretion of potassium was within the normal range of 40-80 mEq/24 hours but was considered to be elevated when viewed in the

light of the existing hypokalemia. The highest value for the specific gravity of the urine was 1.015. A preoperative electrocardiogram (Fig. 1) showed persistent nonspecific changes of the ST segments and T waves consistent with, but not diagnostic of, hypokalemia. No U wave was apparent.

Surgical Findings

As the clinical picture and results of chemical studies were typical for aldosteronism, surgical exploration was undertaken before the report for excretion of urinary aldosterone was available. During the immediate three-day preoperative period, potassium chloride was administered, the dosage being one gm. given three times daily.

On June 27, 1963, the right adrenal gland was explored using a posterior approach through the bed of the twelfth rib. A yellow tumor, slightly less than 2.0 cm. in diameter, was found in the central portion of the right adrenal gland. The entire gland with the

#Results of renal concentration test.

contained tumor was removed. The postoperative course was uneventful. Supplementary potassium was not administered postoperatively despite hypokalemia (serum potassium: 2.5 mEq/L) in the first postoperative day. Subsequently, the levels of serum electrolytes reverted to normal ranges. The patient was discharged on the ninth postoperative day.

Clinical Progress

In September 1963, the patient developed increased sensitivity to cold, insomnia, and aching and cramping of the muscles of the legs. In November 1963, nervousness and palpitations were experienced for the first time and occurred once or twice a month. Since spring of 1964, the patient has experienced dull frontal headaches and occasional unilateral sharp, burning cephalgia. Sixteen months after operation (October 11, 1964) symptomatic improvement was equivocal. The patient had always been warm prior to surgery. At no time during the period between operation and re-evaluation had the muscular symptoms become so incapacitating as before operation.

Blood pressure readings obtained periodically during routine office visits in the postoperative period ranged from 140-150 mm. Hg systolic and 100-110 diastolic.

When the patient was admitted for reevaluation, physical examination revealed a blood pressure of 130 mm. Hg systolic and 95 diastolic in the left arm, and 126 mm. Hg systolic and 86 diastolic in the right arm. The respiratory rate was 18 per minute and the pulse rate 76 per minute. There was no significant change in body weight. No abnormal physical findings were observed.

Multiple laboratory studies were done, the results of which were normal. These included a serum potassium level of 4.0 mEq/L. The level of protein-bound iodine was 3.9 ug/100 ml. of serum (normal range, 3.5-7.5 ug/100 ml.). Uptake of I^{131} by the thyroid was 12.4 per cent after 24 hours. The basal metabolic rate was -2 per cent.

The Adrenal Tumor

The pathologic specimen removed at operation (Fig. 2a) consisted of an adrenal gland in the center of which was a discrete, well-circumscribed, bright yellow, homogeneous, 1.8-cm. nodule. Histologically the tumor resembled a typical cortical adenoma (Fig. 2b). The polygonal and hexagonal cells, having clear and lacy cytoplasm, were closely packed. Nuclei were hyperchromatic and exhibited a moderate degree of pleomorphism.* No mitotic figures were identified. The tumor cells were supported by delicate fibrous septae. The structure of the adenoma bore some similarity to that of the zona glomerulosa of the adrenal gland. The adjacent adrenal cortex was atrophic. In sections stained with hematoxylin and eosin, cells in the zona fasciculata and zona reticularis exhibited a deep eosinophilic hue.

Discussion

In all major aspects the case presented represents a classical example of primary aldosteronism. The muscular tetany, polydypsia, polyuria, nocturia, and paresthesias which were present are typical. The degree of hypertension in our case was milder than that in some others reported.[2] Results of laboratory studies typical for this condition included hypokalemia, mild hypernatremia, elevated carbon dioxide content of the blood and a moderate but definite increase in urinary aldosterone. Normal values for urinary 17-hydroxycorticosteroids and 17-ketosteroids were obtained. The electrocardiographic changes were consistent with those of hypokalemia. Our case showed neither the mild proteinuria nor persistently alkaline urine frequently observed by others.

Primary aldosteronism[2] occurs more commonly in the female than the male by a ratio of about 2.5 to 1. Seventy per cent of all cases occur in the fourth and fifth decades of life. Pathologically, 90 per cent of the cases have a unilateral solitary adenoma. Multiple adenomas are observed in the remainder, and in a few of such cases the tumors are bilateral. In the light of these data, the decision in our case to explore the right adrenal gland first was, indeed, fortuitous.

The vast majority (about 80 per cent) of adenomas are small, each weighing less than six gm. and measuring three cm. or less in diameter. Accordingly, it is doubtful whether any roentgenographic studies such as retroperitoneal air insufflation or aortography would delineate many of the tumors which are responsible for aldosteronism. The diagnosis depends on clinical and laboratory information. Since the *sine qua non* for diagnosis is the finding of hypertension and hypokalemia, the clinician should firmly establish the existence of hypokalemia in a hypertensive patient before performing sophisticated and expensive investigative procedures.

---

*See Test Your Word Score, page 627.

Levels of free urinary aldosterone are usually, but not invariably, elevated. In cases in which the levels are not elevated, increased levels of derivates of aldosterone (tetrahydroaldosterone) have been detected.[2,5]

Originally, the finding of a benign type of hypertension and hypokalemia afforded an important clue to the diagnosis of primary aldosteronism, but reported experiences indicate that in some cases the hypertension may be of the malignant type.[6] Furthermore, primary malignant hypertension itself may manifest aldosteronuria and hypokalemia. In such cases, there is a tendency for hyponatremia to occur in contrast to the hypernatremia associated with primary aldosteronism.[2]

Conn[2] described a variant of primary aldosteronism called congenital aldosteronism. This condition, which is observed in the first two decades of life, is characterized by the presence of polyuria, polydypsia and hypertension, and by the absence of neuromuscular symptoms. Pathologically, each adrenal gland is hyperplastic.

A point of significance in the differential diagnosis of primary aldosteronism is that it may be simulated by unilateral renal disease.[7-9] Frequently in the latter condition, the 24-hour excretion of protein is markedly elevated in contrast to low grades of proteinuria that characterize primary aldosteronism.[9] Also, the response to sodium restriction may differentiate between the two entities. In subjects with primary aldosteronism, limitation of intake of sodium causes a gradual rise in levels of serum potassium, while in cases of unilateral renal disease the hypokalemia may be unaffected by restriction of intake of sodium.

In recent years a syndrome closely resembling that of primary aldosteronism has been described in the French Literature[10-12] as resulting from excessive ingestion of extract of licorice by "cured" alcoholics who had become addicted to licorice. The signs and symptoms described are as follows: flaccid quadriplegia or quadriparesis, paresthesias, tetany, weakness, polyuria, polydypsia and hypertension. Chvostek's sign was elicited in one case. Laboratory studies reveal a hypokalemic alkalosis, elevated levels of carbon

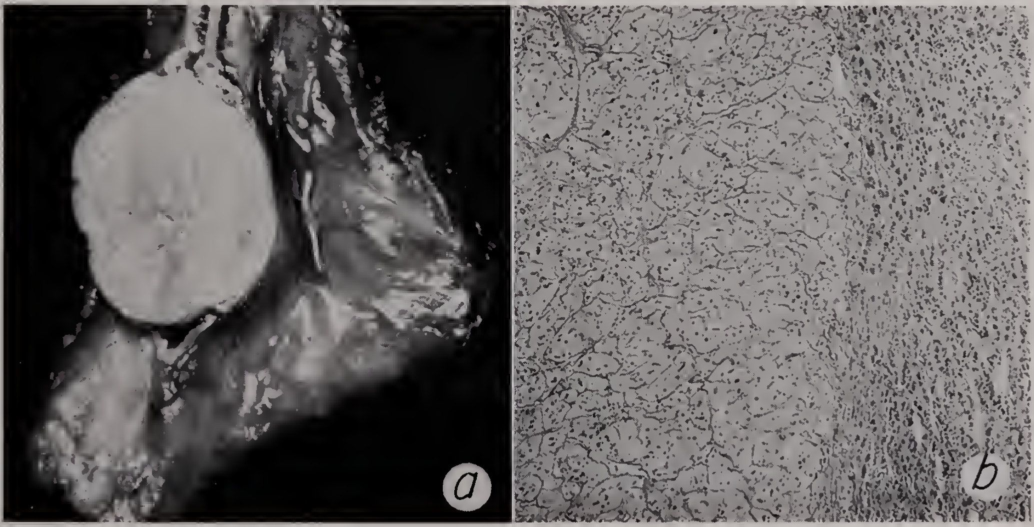

Fig. 2 — Surgically removed right adrenal gland *(a)*. Gross specimen. Cut section of tumor reveals its discrete character. *(b)*. Photomicrograph of junction of the tumor (left side of illustration) and adjacent adrenal gland. Tumor is typically cortical in nature. H & E; x 75.

dioxide in the blood, moderately elevated levels of serum sodium, persistently alkaline urine, and normal urinary 17-ketosteroids and 17-hydroxycorticosteroids. In contrast to primary aldosteronism, the levels of aldosterone in the urine were low. Investigators postulate the close chemical similarity of licorice and DOCA to explain the peculiar biochemical effects. It is doubtful whether clinicians in the United States will have to include this "pseudo-Conn syndrome" in their differential diagnosis.

The basis for a diagnosis of aldosteronism in the case presented seems to be relatively evident. Yet a number of clinical states, such as renal tubular disease,[13] aldosteronism with renal artery stenosis, Cushing's syndrome, and licorice poisoning, must be differentiated from primary aldosteronism. Findings as in the case presented can usually be separated from findings in these other entities by the specific changes noted herein, particularly the normal values for urinary 17-ketosteroids and 17-hydroxycorticosteroids, while the levels for urinary excretion of potassium are high.

Summary

The principal features of primary aldosteronism in a 38-year-old woman included weakness of the lower extremities, paresthesias, polydypsia, polyuria, nocturia, hypertension, hypokalemia, hyposthenuria, elevated levels of aldosterone in the urine and normal urinary levels of 17-hydroxycorticosteroids and 17-ketosteroids.

Treatment consisted of surgical extirpation of the right adrenal gland in which a cortical adenoma was present. Although reevaluation 16 months following operation demonstrated a labile type of hypertension and equivocal symptomatic improvement, the levels of serum electrolytes were normal.

Once medication with thiazides has been excluded, the differential diagnosis includes unilateral renal artery stenosis, Cushing's disease, malignant hypertension, and the excessive ingestion of licorice.

Astrology and Medicine — Virgo, the Virgin

Virgo, sun sign from August 22 to September 22, is visible May evenings in zodiacal transit about midway between the horizon and the zenith, the head and shoulders of the figure near the point where the celestial equator crosses the ecliptic. Virgo represents a virgin holding in her left hand a spike of grain — denoted by the bright 1.2 magnitude star, Spica (spike). In scanning the southern sky after a casual acquaintance with the constellation as delineated on any stellar chart, the interested stargazer is advised to first locate the brilliant Spica and then orient around it from memory the lesser magnitude stars that comprise the total constellation of Virgo.

Astrologically, Virgo governs the intestines and therefore, under adverse influences, promotes vulnerability to abdominal diseases and disorders. Since these are often notoriously elusive to locate and ambiguous in symptomatology, the astrotherapist can presumably arrive at a quicker, more accurate diagnosis by abandoning the routine examination of the abdomen and substituting the unorthodox approach known in Astrology as "eye-diagnostics:" "the science of ascertaining the nature and seat of a disease of different parts of the body from discolouring and other indications in the Iris."*

The origin of "eye-diagnostics" makes an interesting if incredible story: "Ignaz Peczely, a Hungarian, discovered this method. When a boy, he once caught a large owl. The bird defended himself furiously and clawed his talons deep into Ignaz' hand. In order to free himself of the clutch, the boy was compelled to break the leg of the owl with his free hand. The moment he did so, he saw a dark stripe shoot through the lower part of the owl's eye (through the Iris) and at the same side where he had caused the fracture. He dressed the leg, which after some time recovered and he now noticed that according as the process of curing advanced, the dark line became surrounded by a narrow light-colored line, as if it were wrapping the sick place round with a protective layer. This began his research in this line, — which ended in giving quite a new method of diagnostics. Gradually he got to know the exact places in the Iris in which the different parts of the body are indicated by observation of his patients. To the expression "the eye is the mirror of the soul" we may therefore add according to this doctrine, "and of the body."**

Patient Positioning

with an Automatic Bed Positioner

CLAUDE R. HITCHCOCK, M.D., Ph.D.*
Minneapolis, Minnesota

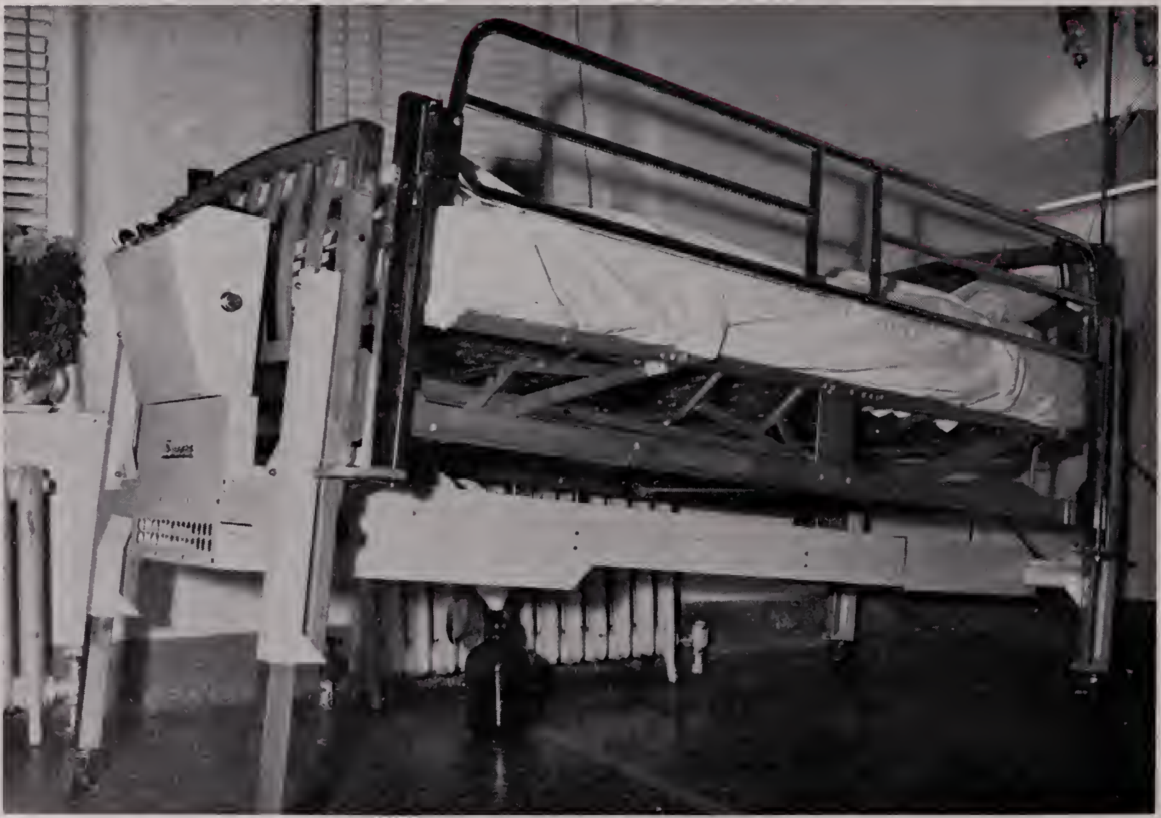

Fig. 1 — Patient positioning.

PRESENT DAY refinements in therapeutic techniques have brought a need for improved management of the bedridden patient from the standpoint of his general body "position." Surgeons usually practice early ambulation of their postoperative patients wherever possible, knowing that postoperative complications are thereby reduced in number and severity. In some medical illnesses, for example those affecting the cardiovascular and pulmonary systems, posture of the patient can be of major therapeutic significance.

The general physiologic "well-being" of bedridden patients has become the principle interest of physiotherapists and specialists in physical medicine. However, the growing number of bedridden elderly patients and seriously traumatized accident victims presents an overwhelming problem from the standpoint of adequate physical therapy during prolonged periods of bed rest. The advent of a new mechanical method to assist in the better and more physiologic care of our patients confined to bed for long periods could be of great value to all groups in medicine. This communication presents a newly conceived device of this kind.

Detrimental Physiologic Effects of Prolonged Sedentary Bed Rest

Normal vigor and healthy tone of body tissues depend on frequent change of position. Prolonged rest of muscle groups leads to a disuse atrophy of muscle cells and supporting structures such as tendons and fascia. Disuse atrophy is commonly found in muscle and other soft tissues as well as in bone in the form of osteoporosis. Factors of repeated stress and strain are important for the health of soft tissues as well as of the skeleton, for tissues add materials necessary for maintenance and growth in answer to the demands of physical stress. Specific physiologic alterations have been shown to result from immobilization of areas of the body with plaster fixation.

Howard et al.[1] and Deitrick et al.[2] have shown that calcium output increases for several weeks and then remains at an increased level in bedridden patients. Nitrogen is also lost, and it can be accepted that calcium and protein are both lost more rapidly from the body under conditions of prolonged immobilization than in normal situations of exercise. It has been shown that the deposition of calcium into the bony matrix is not disturbed, but there is a reduction in the deposit of new protein bone matrix. Under conditions of prolonged immobilization and lack of recurring stress the absorption of mature osteoid continues and a true disuse atrophy results.

Prolonged immobilization is accompanied by an increase in urinary and fecal excretion of calcium. In some studies the calcium content of urine was doubled during immobilization of various portions of the body. Also an increase in excretion of phosphorus, total sulphur, sodium and potassium has been found. As patients begin physical activity during their recovery periods a retention of nitrogen, calcium, phosphorus, sulfur, and potassium has been demonstrated.

Over the years clinicians have learned to recognize the occasional extreme degrees of osteoporosis which are found in chronic invalids bedridden for many months. Ligaments supporting vital internal abdominal organs lose their tensile strength during continued and prolonged recumbent positioning, and even in younger individuals a state of advanced aging of the tissues can be demonstrated. Optimal tensile strength of the connective tissue stroma of the body depends in large measure upon a continual changing stress and strain created by differential tensions between various organs of the body. Over the years there has been ample evidence to support the aphorism that — "As activity decreases, aging increases."

Corrective Measures to Combat the Sequelae of Immobilization

Forearmed with the knowledge that generalized states of osteoporosis and muscle wasting will follow prolonged bed rest it is logical to attempt always a minimum necessary time of complete bed rest. Ordinary and uncomplicated surgical procedures in good risk patients can usually be followed by early ambulation within 36 to 48 hours. Such early mobilization is now considered the "sine qua

---

non" for reduction of postoperative complications such as thrombophlebitis, prolonged ileus, atelectasis, and other pulmonary sequelae.

In those situations where patients are confined to bed in traction following trauma or complicated orthopedic surgical procedures, active and vigorous physiotherapy moving all possible joints and muscle groups is helpful. However, in many hospitals the personnel available for physiotherapy are limited in number and restricted in the amount of attention they can direct to a given patient's problem. In lieu of adequate physiotherapy a patient confined to bed for a prolonged period can be constantly changed in position so that the muscle mass of the body moves in a differential relationship to the skeleton at frequent intervals.

Gentle muscle mass and tendon traction on the skeletal system created by a repeated change in position which makes use of differential gravimetric pull can provide effective passive exercise which tends to restore vigor and vitality of the tissues. Unfortunately, in most hospitals such continual movement of a patient must be performed by nursing and ancillary personnel, and such a program is burdensome and incapable of accomplishment with present staffing problems.

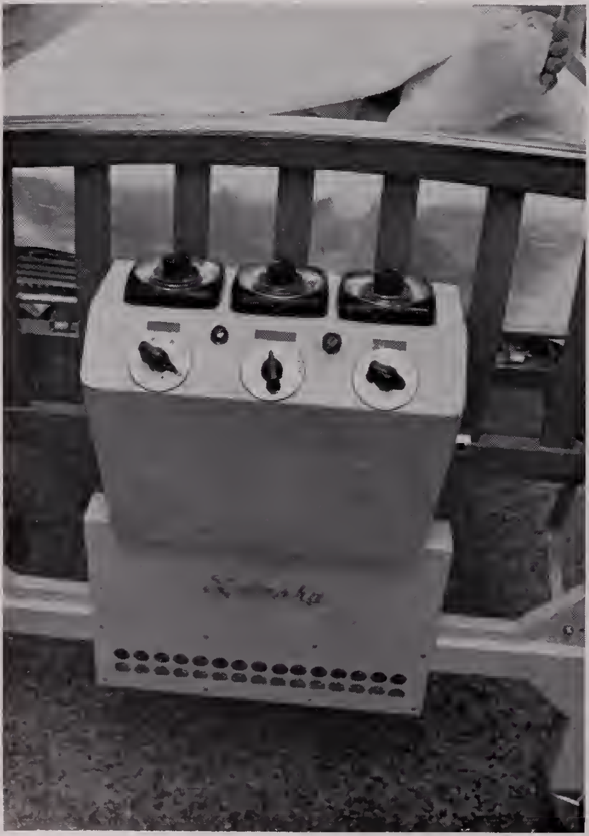

Fig. 2 — Instrument panel.

Previous experience of the author with osteoporotic patients on a rapidly oscillating (poliomyelitis type) bed has shown a remarkable reversal of urinary excretion of calcium with improved ossification of bone.[3] In this experience the negative calcium balance induced by severe skeletal metastases of breast cancer was reversed by the simple expedient of creating a tension between the shifting mass of muscle and the gravimetrically different skeleton. For most patients, however, a vigorously oscillating bed is an annoyance. This paper presents a newly designed and constructed mechanical bed alternator to accomplish this physiologically desirable change of position on a continual basis. Thus, a mechanical device can be utilized to produce a more healthful and physiologically acceptable environment for the bedridden patient.

Versatile Automatic Bed Positioner

This electrically driven unit has been designed for simple placement under a standard hospital bed (Figure 1). Adjustment of the length of the legs of the hospital bed for overall height will permit the mattress of the hospital bed to be at a standard height from the floor or at a somewhat reduced height for easy movement of the patient. The essential feature of this bed positioner is the ability to raise either the head or the foot of the bed independently and in a controlled time sequence. The mechanical system utilizes a quiet two-way motor and a system of ball-bearing pulleys and steel cable for the mechanical connections. During engineering construction of the prototype unit a hydraulic system was found to be too noisy for practicable use.

During elevation of either the head or foot of the bed the height of rise can be adjusted from two inches to twelve inches. Selector dials on the control panel at the foot of the bed are available for choosing the desired height of elevation. A master selection switch permits a choice of alternating a head-elevated and lowered sequence without involvement of the foot of the bed. In a similar manner, the selection switch will permit a foot-rising sequence of the bed which is independent of action of the head of the bed. The third choice in the master selector switch permits an alternation of the head-elevated position with a foot-elevated position.

Three electrical timers are incorporated into the control panel (Figure 2) and permit a choice of time from one-half minute to one hour in any given position. Thus, the head may be elevated to a desired height for a variable period of time, the bed returned to a flat position for a specific period of time, and the feet elevated to a desired height for a variable period of time. This maximum controlled setting is automatically repeated until the shut-off switch is used to stop the action. Through a proper choice of dial settings the following combinations can be achieved:

1. *Elevation of head* alternated with a *flat bed position* for a variable time of elevation and flat position from one-half minute to one hour.
2. *Elevation of the foot* alternating with the *flat position* and with time variable from one-half minute to one hour.
3. The *head-elevated position* can be alternated with a *flat position* which in turn can be immediately alternated with a *foot-elevated position,* and the entire cycle controlled for varying and different periods of time for the head-elevated, foot-elevated, or flat position.
4. With a short time interval of one-half minute for each specific position and an alternation of head elevation with flat bed position with foot elevation a gentle and slow continuous change of position from feet elevated to head elevated can be achieved.

From the foregoing description it is apparent that, for any given position of elevation of either the head or the foot of the bed, the variable factors are the height of the unit and the length of time such an elevation is maintained. Complete selectivity of operation is provided for any desired pattern of motion.

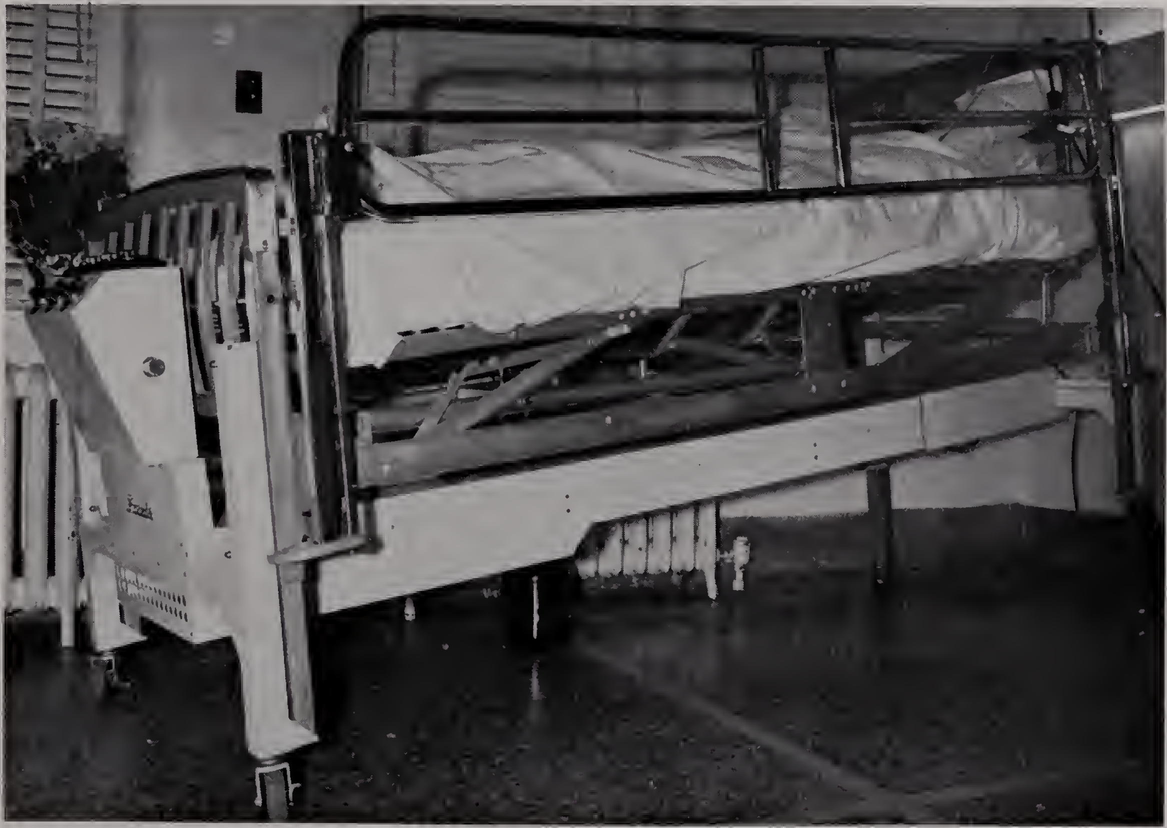

Fig. 2 — Bed positioning.

Standard hospital services are not interfered with, for the unit leaves the area under the patient's bed unencumbered (Figure 3). Suction devices, urine jugs, and other necessary appliances at the bedside can be maintained without difficulty. The alternator unit is mounted on four-inch rubber-tired casters for easy mobility about the hospital. Insulation in the mechanical chamber reduces noise to a barely audible hum. The instrument panel (Figure 2) is mounted at the foot of the bed in a convenient position for operation but without interfering with the sides of the bed. The only requirement for satisfactory operation of the alternator unit is a standard 110-volt electrical outlet.

Application for the Postsurgical Patient

Postsurgical patients who will benefit from a slight Trendelenburg position for a few hours for stabilization of a fluctuating blood pressure can have the foot of the bed elevated to a desired height (two to twelve inches) and for a specific period of time up to one hour. This position can be alternated with a flat bed position or a head-elevated position as desired. A pattern of foot elevation alternated with head elevation in a time sequence of approximately ten minutes for each will reduce the problem of venous pooling in the extremities, will aid venous return to the heart, and will improve pulmonary function periodically.

It is recommended that the head-elevated position be used at a maximum of twelve inches and the foot-elevated position be used at six to eight inches for the routine postoperative patient. During use of the bed positioner all other nursing and supportive functions such as chest catheter suction, nasogastric suction, urinary catheter drainage, biliary tract drainage, etc. can proceed without interference,

Patients Needing Prolonged Bed Rest Following Trauma

Patients confined to bed for prolonged periods in body spicas or extensive plaster casts can benefit from frequent position change. Particularly those patients lying quietly with skeletal traction on both lower extremities as well as upper extremities need a frequent change of the muscle mass relative to the axial skeleton to maintain general body tissue tone. In these situations a constant alternation between maximum head elevation (twelve inches) and maximum foot elevation (twelve inches) with comfortable time intervals at the flat position can provide necessary and beneficial physiologic exercise to the patient. The obvious freedom from attention by nursing and ancillary personnel is noteworthy.

Even with a short-time setting of one-half minute at the head-up or foot-up position the bed positioner function is well tolerated by the patients and they soon become acclimated to the repetitious and frequent body change. Since the standard hospital bed is used, all necessary supporting framework and pulleys for orthopedic skeletal traction can be used indiscriminately. An additional feature in this application is the ability to change the tension and pull of the muscle mass differentially with the skeleton by change of position without interference at any time with the positioning of guy wires for the traction apparatus. Indeed, physiologic bed positioning is achieved with a minimum of disturbance to the patient.

Patients with the Postphlebitic Syndrome

The swelling and chronic edema suffered by the patient following severe deep thrombophlebitis poses many problems in management. Patients of this type benefit greatly from a foot-elevated position for the portions of time when they are at rest. These people should refrain from prolonged sitting in the upright position and should attempt at all times of rest to have their feet elevated slightly above the level of the heart. Commonly, however, these patients are of an older age group and their pulmonary function is compromised slightly by a foot-elevated position if it is prolonged. The use of the automatic bed positioner for ordinary sleep during night hours could achieve both the benefits of the foot-elevated position alternated with the flat or supine position for maintenance of pulmonary health. Only by use of a unit of this kind can such a degree of flexibility be automatically achieved.

Patients with Peripheral Vascular Problems

Older individuals with impaired peripheral circulation frequently benefit from a head-elevated position as they recline in bed. However, venous return is compromised and difficulties from varicose veins and stasis in the peripheral venous bed prevent prolonged dependency of the feet. The use of an automatic bed positioner for alternately raising the head and lowering the bed to a flat position for specific periods of time can greatly improve the management of such difficult cases.

Patients afflicted with venous problems which are aggravated by the dependent position of the lower extremities (varicose veins) are improved when rest is achieved with a mild elevation of the foot of the bed. Pulmonary disease, however, commonly is present and frequent change of position to either a flat or a mild head-elevated position can be helpful. The automatic bed positioner unit can achieve a nicely varied balance for patients of this kind.

Patients with Myocardial Infarction

The patient suffering a myocardial infarction from coronary occlusion commonly does best when treated in a semi-sitting position. However, the general circulation as far as the extremities are concerned benefits from at least a supine positioning or a mild elevation of the feet periodically. Further, such patients who are bedridden for prolonged periods of time would benefit from the differential action of muscle mass on the axial skeleton.

Summary and Conclusions

An automatic bed positioner has been developed to assist patients bedridden for prolonged periods of time and who will benefit from constant change of body position. Shifting of the muscle mass of the body in relation to the axial skeleton has been known to improve the general bone health as well as the general tone of fascia, connective tissue, and muscle mass. Applications for this kind of automatic unit are wide and cover the entire spectrum of disease.

The unit presented has an unusual degree of flexibility and is ideally constructed to be applied to any standard hospital bed. Patients suffering from chronic diseases requiring prolonged hospitalization and bed rest can be more readily maintained in a state of good tissue tone by the use of this kind of automatic positioner.

Moderate Hypothermia

DAVITT A. FELDER, M.D.
St. Paul, Minnesota

THE HAZARD of even temporary complete occlusion of an extracranial carotid artery in adults has long been recognized.

The damaging effect of arteriosclerotic lesions and congenital changes on the collateral pathways in the circle of Willis with extracranial obstruction in addition to this was pointed out by Hunt in 1914.[1] However, it was not until more recently that extracranial thrombotic obstruction of the carotid artery has become associated with the clinical entity of stroke of completed, intermittent or progressive types as described by Gurdjian and Webster in 1953.[2] These authors resected the thrombosed portions of the carotid arteries to effect a sympathectomy of the distal cerebral arterial tree. With this there began to appear reports of the successful surgical treatment of other extracranial carotid and vertebral arterial lesions of aneurysmal[3] and stenotic types in patients[4] with symptoms of cerebral ischemia. Although there was encouraging success in these reports, surgical occlusion of the extracranial carotid arterial system was still accompanied by irreparable brain damage in some instances.

Early in our experience with surgery of the extracranial carotid arteries it became apparent that patients with completed strokes in the acute phase were not, as a rule, candidates for immediate surgery. From 1955 to January 1958, five such patients were operated upon, only one of whom showed improvement.

Although this was a small sample it was decided to reserve carotid surgical treatment for those stroke patients who were recovered and for those with progressive or intermittent cerebral ischemia who might benefit from increasing the cerebral arterial circulation. However, there still remained the possibility of irreversible brain damage in patients during occlusion for repair of a stenotic or compromised carotid artery which represented a critical blood supply to the brain. It was thought that total-body hypothermia might be effective in preventing cerebral damage in these cases.

Rosomoff and Holaday, in 1954,[5] showed in dogs that with each degree centigrade drop in body temperature the cerebral blood flow and oxygen consumption of the brain dropped 6.7%. They found that as long as respiratory and cardiac functions were maintained, no ischemia of the brain would result.

Marshall, Owens and Swan, in 1956,[6]

showed that with total body hypothermia in dogs the entire major and collateral cerebral circulation could be occluded for three times as long as in the normothermic animals without significant brain damage. In that same year Stone, Donnelly and Frobese[7] studied cerebral blood flow and metabolism in three routine surgical patients, using hypothermia of 82.6° F. to 84.8° F. as an anesthetic adjunct prior to surgery. Their findings showed that if shivering were controlled, there resulted a drop in cerebral metabolism of 76% of normal with the reduction of body temperature down to 83° F. Upon this they postulated that the cerebral blood supply could be shut off for three times the accepted 3-minute time length with impunity.

In the treatment of intracranial aneurysm (22 ruptured and one unruptured), Botterell, Lougheed, Scott and VanDewater[8] cooled patients down to 86° F. and temporarily occluded the carotid and vertebral inflow, when possible, for a period of six minutes while the intracranial aneurysm was clipped. There were 19 survivors, in 16 of whom the result was good from the cerebral standpoint.

Selection of Patients for Hypothermia

Based on these studies and on our previous experience with deep hypothermia in cardiovascular cases it was decided that moderate hypothermia should provide some measure of protection without the hazards previously encountered with deep hypothermia. Moderate hypothermia was used then for patients with lesions thought to require occlusion of an artery representing a significant or critical portion of the blood supply to all or a portion of the brain. This included patients who developed signs of acute cerebral ischemia on preoperative trial occlusion of the artery in question; those showing no intracranial crossover from the opposite side on angiographic studies; and patients with frank angiographic occlusions of all carotid or vertebral arteries except the vessel to be repaired or bypassed.

Visualization of collateral vessels smaller than the vertebral arteries in no instance was considered adequate for maintainance of blood supply during carotid occlusion.

Procedure

A total of 42 operations were done on 36 patients, most of whom were in the seventh decade of life. Twenty-two were made hypothermic by use of a cooling blanket, requiring from three to four and one-half hours to get the body temperature down to the 85° F. to 90° F. range. In most instances the cooling was stopped at 90° F., after which the temperature would drift down to around 86° F., when it was thought optimal to proceed with carotid occlusion. In a few patients it was difficult to attain the 86° F. level even after four and one-half hours of hypothermic effect. These were usually thick-set, muscular individuals.

In two of these patients an internal bypass was used. The occlusion times varied from nine to 22 minutes, with the mean occlusion time at 14.2 minutes.

Results

The clinical results in this series are examined principally from the standpoint of evaluating the possible beneficial or deleterious effects of moderate hypothermia and not as an evaluation of extracranial carotid artery surgery alone. The latter is definitely a consideration in our series but not of primary concern in this study except for possible limited comparison.

Four categories suggest themselves as a description of the clinical status at the end of the hospital stay. These categories are "worse," "no change," "improved," and "expired."

In instances where the postoperative state at the time of discharge from the hospital showed any clinical neurological deficit not documented prior to surgery, the condition is described as "worse." The "no change" category includes those patients whose postoperative status after 48 hours was apparently no different from the preoperative condition. In the "improved" group are those patients who were clearly better clinically at the end of their hospital stay, with appreciably fewer or no signs of the neurological deficit present preoperatively. The "expired" group describes only inhospital deaths. There were no operative deaths.

Improved

Table 1 shows the over-all results in patients operated upon under hypothermia. Fourteen of the 18 patients operated upon under hypothermia requiring occlusion showed improvement. In four other patients using moderate hypothermia the carotid artery was not opened, but constricting bands, or kinking, were removed and stenosis relieved at surgery. Two of these showed improvement.

Table 2 shows the results in those patients with carotid artery surgery requiring occlusion in the normothermic state. Of 16 such procedures 10 resulted in improvement.

The over-all results in reparative carotid artery surgery requiring occlusion are shown in Table 3. Of the 34 operations in this group, 24 resulted in improvement.

The over-all results in the entire series are shown in Table 4. Of the 42 procedures, 26 were followed by improvement.

Improved Cerebration

In three patients with progressive mental clouding, memory loss, and loss of affect, there was a remarkable recovery of cerebration to an alert sensorium* with a return of memory function and affect. In two instances the improvement was enhanced with each of two succeeding right and left carotid artery restorations of normal flow.

Uninvolved Carotid Artery

In three instances the carotid artery was found to be uninvolved to any significant degree, despite an angiographic appearance of an arteriosclerotic stenosing lesion. In one

of these the carotid was kinked. None of these vessels were opened (Table 1).

Complications

The complications in this series were neurological, cardiac, and hypotensive. They occurred in six patients, some of whom developed neurological complications, others cardiac or postural complications, still others a combination of two.

Neurological

In one patient operated upon under normothermic conditions an *hypoglossal nerve paresis* was noted on the operative side immediately after surgery and was gone in 48 hours. This manifested itself by deviation of the tongue to the operated side and some slight difficulty in swallowing.

In a second patient operated upon under hypothermia a marked, *generalized muscular spasticity* developed on the contralateral side immediately after surgery, as well as an hypoglossal paresis on the operative side. Both of these neurological deficits were gone in 48 hours. This patient was a very muscular 64-year-old white male in whom a temperature of only 89° F. could be reached after four and one-half hours. Because of this an internal shunt was used, but even with this the total occlusion time was 16 minutes. He was found to have occlusion of both vertebral arteries and a marked stenosis of both internal carotids on angiographic studies. After complete recovery from the first operation the patient was subsequently operated upon on the opposite side to provide the safety factor of a collateral circulation. Except for an inability in accurate computation of multidigital problems of even simple types, he was well for three years after his first surgery. This is the one patient listed as "worse" postoperatively. He died nine months after his second carotid surgery.

Postural Hypotension and Neurological Deficit

A 62-year-old white male operated on under normothermic conditions developed a *right-sided weakness with postural hypotension* one week postoperatively. Both of these conditions gradually cleared in another week. No cardiac abnormalities were found. It is interesting to note that throughout this episode one could palpate the internal carotid artery pulsation intrapharyngeally. The patient has been very active for four and one-half years following surgery without any episodes of hypotension or neurological deficit. He still has a palpable intrapharyngeal pulse in the internal carotid.

A second patient, a 72-year-old man, was operated upon under hypothermia at 86.5° F. and developed *a facial weakness* on the operated side which lasted for 24 hours postoperatively. It is interesting that this patient,

Asymptomatic	0	1	0	0	1
Totals	1	11	26	4	42

operated upon for mental obtundity and lethargy, made an excellent symptomatic response but developed a hypotension immediately postoperatively, requiring vasopressor drugs to maintain a systolic blood pressure over 100 millimeters of mercury. This condition persisted for the first 24 hours after surgery, and his facial weakness was noted to disappear concomitantly with his spontaneous maintenance of a normal blood pressure without medication. No evidence of myocardial damage could be found. This patient has been remarkably alert for the past six months since his surgery and has no other neurological deficits.

Cardiac

A 63-year-old white female was operated upon under hypothermia for a cervical-cephalic extension syncope of two months' duration after a left hemiparesis from which she completely recovered. A total right-carotid-artery thrombosis and a marked left-carotid and bilateral vertebral-artery stenosis were found angiographically. Hypothermia was used, and since the temperature was only 89° F. after four and one-half hours and the blood pressure unstable, an internal shunt was used. The total occlusion time was 14 minutes. Postoperatively the patient was apparently recovering nicely without neurological deficit when she was noted to have a left-sided weakness on the fifth postoperative day. This persisted for two days, and on the eighth postoperative day she developed dizziness unrelated to cervical-cephalic extension and was noted to have *atrial fibrillation and electrocardiographic evidence of myocardial ischemia.* The blood pressure, however, remained normal during this period. Both the electrocardiographic picture and the clinical symptoms disappeared with bed rest and cardiac medication over the next few weeks, and the patient was discharged from the hospital asymptomatic. She expired four and one-half months later of what was thought to be a cerebral vascular thrombosis.

Another 51-year-old male operated on under moderate hypothermia suffered a *myocardial infarction and cardiac standstill* six hours postoperatively. He was revived by external cardiac massage and electrical defibrillation. He survived for 12 more days without apparent sequelae, when he again had a cardiac standstill and could not be revived. Post-mortem examination showed massive, old and recent myocardial infarctions. This case represents the only acute or inhospital death among the patients operated upon under moderate hypothermia.

Deaths

In this series there were nine deaths. Four of these occurred while the patients were still hospitalized and five from three months to five years postoperatively.

Hospital Deaths

Of the acute inhospital deaths two were of patients who had carotid embolectomy procedures and both were due to recurrent multiple or generalized embolism: one 24 and the other 48 hours postoperatively as shown at post-mortem examination. The third patient in this group expired 36 hours after surgery and was found on surgical exploration to have a completely thrombosed carotid system from the subclavian origin to the skull. No attempt at reparative surgery was made. On post-mortem examination the thrombosis was found to involve the circle of Willis also. The latter three patients were all operated upon under normothermic conditions.

A fourth patient operated on under moderate hypothermia suffered a myocardial infarction and cardiac standstill and is described above under "cardiac complications."

Late Deaths

Of the late deaths three were thought to be due to intracranial cerebral vascular thrombosis. This was shown by autopsy in one case at four and one-half months. The second patient had the clinical diagnosis made at death four and one-half years postoperatively with no post-mortem examination. The third of these patients, who expired of what was thought to be a cerebral vascular accident 19 months postoperatively, also had no post-mortem examination. It is worthy of note that this is the only patient in the entire series who developed an aneurysmal dilatation of the endarterectomy site, which might possibly have been a source of emboli and secondary intracranial thrombosis. He was also known to have metastatic adenocarcinoma, presumably from a primary lesion in the colon resected before the carotid endarterectomy was done.

A fourth late death occurred three months after surgery. This patient died of a generalized septicemia, meningitis and suppurative myocarditis shown at post-mortem examination.

The fifth late death occurred at nine months after surgery and was thought to be due to an acute coronary insufficiency. This patient had had two episodes of cardiac failure with pulmonary edema within the previous six months prior to his death. No postmortem was obtained.

Discussion

For the most part in the literature the process of selection for surgery is in terms of the clinical symptomatology and physical findings. No differentiation, separation or exclusion on the basis of angiographic patterns is reported for whole groups. For this reason it is difficult and probably invalid to compare our results with those in the literature. Here preselection before surgical consultation or after angiographic studies may represent a major factor in evaluating results. Our patients operated upon under hypothermia may represent patients not given the benefit of surgery in other centers. Certainly we would have turned down many of these if hypothermia had not been available.

The Occlusion Time

A comparison may be made, however, with the results of series in which a comparable range of hypothermia was used and where complete cerebral occlusion was used for the treatment of intracranial aneurysms as reported by Karlsberg and Adams.[9] They found in their series of 54 patients that when occlusions lasted 10 minutes or less, 60% of the patients made a satisfactory recovery. With longer occlusion times only 30% made good recoveries.

Cardiac Risk

There were two instances of cardiac arrests and one of myocardial infarction. The more extensive surgery involved in opening the mediastinum for total root-vessel occlusion certainly could have played a part here. The one instance in our series of myocardial infarction with arrest six hours after surgery could have been precipitated by the hypothermia and anesthesia. This complication must be expected in any series of patients operated upon for lesions of an arteriosclerotic nature. Our prior experience with hypothermia in this range has not been attended by an increased incidence of myocardial infarction or of cardiac standstill. An already compromised coronary circulation may increase myocardial irritability and interfere seriously with myocardial conduction during the hypothermic state. We have found no good evidence to explain any enhancement of the thrombotic process in diseased coronaries, although such predisposition to thrombosis undoubtedly exists under these conditions.

Hypoglossal Nerve Paresis

The complications of temporary hypoglossal nerve paresis is undoubtedly related to retraction of the ansa hypoglossi during surgery. This can probably be avoided in most individuals if enough time and care are taken in making the exposure.

Hypotension

The postural hypotension seen in one of our patients with its concomitant neurological deficit and lack of evidence of myocardial damage is not readily explainable. We have no reasonable explanation for the patient with post-anesthesia hypotension and neurological findings. Conjecture as to etiological bases for these manifestations would lead us into many areas of discussion not appropriate to this report. It is probable in cases like these that the opening of stenotic, extracranial carotid artery lesions may relieve symptoms as long as a normal blood pressure exists; but associated intracranial occlusive disease not otherwise manifest may become symptomatically apparent with even a relative hypotension.

The patient previously described with the postoperative unilateral spasticity undoubtedly suffered some cerebral damage as evidenced by his persistent difficulties with simple computation. Although he recovered clinically and with little evidence of brain damage, it is likely that in such instances there remains appreciable tissue evidence of ischemic damage as shown by the experimental work of Rosomoff.[10] Such a patient may be more susceptible to further ischemic insults because of a functionally critical reduction in the number of remaining brain cells. This is an added reason for opening other stenotic extracranial pathways, as was accomplished by the second procedure on the opposite carotid artery in this patient.

Hypothermia Safety Factor

With the exception of the one death due to myocardial infarction and the patient considered "worse" in the hypothermic group, a comparison of the normothermic and hypothermic groups shows little difference in the results. Assuming that the above mentioned death was due to the hypothermia, the results still show that the hypothermic group of 22 procedures with 16 improved, five unchanged, one worse, and one deceased, compares favorably with the normothermic group of 16 procedures with 10 improved, three unchanged and three deceased. Since the hypothermic group consisted of patients with appreciably greater operative hazard, the results are encouraging. These findings strongly suggest that moderate hypothermia provides a significant safety factor for the patient with a critical preoperative reduction in collateral circulation to the cerebrum.

Summary and Conclusions

The results of 42 operative procedures on the extracranial carotid artery are presented. Twenty-two operations done under moderate hypothermia (86°F.-89°F.) for what was thought to be critical reduction of cerebral blood supply are compared with those procedures in this same series with apparent adequate collateral blood supply done under normothermic conditions.

The results show that moderate hypothermia may have a protective effect on the cerebrum in the patient with a precarious cerebral blood supply when operation requires temporary occlusion of that supply.

Treatment of Penetrating Chest Injuries

JOHN F. PERRY, JR., M.D., Ph.D.*
St. Paul, Minnesota

EXPERIENCE GAINED in wartime with large numbers of penetrating thoracic wounds has resulted in sound recommendations for management of such injuries under war conditions. The situation with regard to chest wounds in civil life is less clear, however. Since there is a difference between war wounds of the thorax and penetrating chest wounds as seen in a civilian population, it is not surprising that military recommendations for management are not wholly applicable to the nonmilitary situation and that there exists a variety of opinions as to how the civilian chest injury should be treated. The material to be reported here is an analysis of the management of a group of such injuries seen at a city-county hospital. Although the number of patients is smaller than in several other series of civilian penetrating chest wounds, the recommendations for treatment based on this analysis seem warranted.

Clinical Material

During the period January 1, 1959, through December 31, 1964, 39 patients with penetrating chest wounds were seen at the Ancker Hospital. All patients who reached the hospital have been included, even if they expired in the Receiving Room. As in other reported series, young males were most often injured. The vital statistics of this group of patients are illustrated in the table. Patients ranged in age from 15 to 72 years with an average of 30.5 years. Only five patients were over 40 years of age.

Males	32
Females	7
Single wounds	34
Multiple wounds	5
Stab wounds	19
Gunshot	18
Falling tree	1
Car accident	1
Living	34
Early dead (12.8%	5

In addition to the chest wounds, eight patients had injury to abdominal viscera; two had upper extremity injuries, and one patient suffered partial section of the spinal cord in addition. The majority of injuries were incurred in altercations or suicide attempts.

---

*From the Department of Surgery, Ancker Hospital, St. Paul, Minnesota and the University of Minnesota Medical School, Minneapolis, Minnesota.

Early Death

Three of the patients were dead within less than an hour after arrival at the hospital, and after all resuscitative efforts had failed. One, with a gunshot wound in the heart, was taken to the Operating Room and died during thoracotomy for repair. A 72-year-old male, with a prior history of heart failure, expired five days after he was stabbed in the right chest. Autopsy demonstrated bilateral pulmonary edema and a myocardial infarct. The stab wound had penetrated the diaphragm and punctured the liver as well.

Treatment

Emergency Procedures

The patients received blood transfusions for volume replacement as needed, analgesics and nerve blocks for pain, and meticulous attention to tracheobronchial toilet to prevent accumulation of secretions and wet lung.[1,2]

Thoracotomy and Chest Tubes

The specific treatment most often followed was closed thoracotomy, placement of chest tubes, and blood replacement. Such therapy was employed for 26 patients with only one death. Tube drainage was utilized for from two to 10 days with an average of 4.2. Surviving patients were hospitalized a minimum of four days and a maximum of seven months. For patients whose only manifestation of injury was hemopneumothorax, including those who developed complications related to it, duration of hospitalization averaged 4.6 days, with a median of 10.

Other Treatment

Four patients with minimal hemopneumothorax were treated by observation only and all survived. Thoracentesis was the treatment employed for this complication in three patients, all of whom survived. Thoracotomy was used three times. One patient with a gunshot wound to the heart died during an attempt at surgical repair. The remaining two treated by thoracotomy survived and were discharged after 10 days and one month, respectively. Eight patients had laparotomies as part of the initial hospital treatment. Seven of these were found to have abdominal viscera injuries.

Complications

Air Embolism

Air embolism resulted from the inadvertent introduction of air into an intravenous tubing in one patient who recovered without residual effects.

Wound Infection

Superficial wound infection occurred in one stab wound which had been sutured. This responded to simple drainage.

Intussusception

Ileocecal intussusception occurred following laparotomy in a 35-year-old female who had been treated for multiple stab wounds of chest and abdomen. She required reoperation and recovered thereafter.

Empyema

A 19-year-old male was admitted with penetrating thoracic wound and flail chest. The unstable chest was treated by tracheotomy and intermittent positive-pressure ventilation by mechanical respirator; the right hemopneumothorax was treated by chest tubes and suction. Because of inadequate control of the flail he developed pulmonary edema and pneumonia, and thereafter a right empyema which required drainage by rib resection.

Clotted Hemothorax

One patient with hemothorax was treated by chest tubes and suction. Because of persistent opacity of the hemothorax he later required thoracotomy for removal of clots and decortication of the lung.

Discussion

Hemopneumothorax as a complication of penetrating chest wounds has been treated principally by repeated thoracenteses in battle injuries, and operative intervention has been reserved for continuing hemorrhage and other complications. Chest tubes have been employed for tension pneumothorax, but their use has not been recommended for treatment of hemopneumothorax because of an increased incidence of complications. The results obtained in World War II and the Korean conflict support these concepts as sound treatment for the combat casualty with hemopneumothorax.[3-13]

Though penetrating chest wounds in a civilian population differ in several important respects from those seen in wartime, it cannot be assumed that the same treatment can be utilized and that the same complications will follow. The agents responsible for the wounds are different; civilian injuries are usually treated without delay and circumstances for treatment are more nearly optimal. The physician who sees the patient initially continues to supervise his care until recovery, and there is usually no need to transport the patient to another facility while he still suffers from hemopneumothorax.

Emergency Thoracotomy

Emergency thoracotomy has an important place in management of penetrating chest wounds and, in fact, increased survival rates in these injuries will depend on its more frequent use, when there is shock unresponsive to blood replacement and when it is apparent that massive hemorrhage is occurring in the chest. However, most surgeons[14-17] are agreed that the majority of hemopneumothoraces from penetrating chest injuries should be treated by closed means, either by repeated thoracentesis to evacuate air and blood or by chest tubes and suction for this purpose.

Repeated Thoracentesis

Surgeons who employ repeated thoracentesis for treatment of hemopneumothorax offer impressive results and a low rate of complications in support of this type of treatment.[14-17] Thus, if other types of treatment are proposed, it must be shown that they possess advantages over thoracentesis, that results are equal or better, that hospitalization is not prolonged, and that incidence of complications is not increased.

Chest Tubes and Suction

Chest tubes and suction possess advantages over repeated thoracentesis for treatment of traumatic hemopneumothorax: Air and blood is rapidly evacuated from the chest, the lung is immediately expanded, and the patient's ventilatory capacity is immediately restored. There is no evidence that immediate expansion of lung increases bleeding into the chest.[18-19-20] It is possible to follow accurately the amount of bleeding from the chest by measurement of drainage, and need for early thoracotomy can be readily determined. The necessity for repeated procedures is eliminated by use of chest tubes. The average period of hospitalization of patients treated by chest tubes for hemopneumothorax in this series compares favorably with that of patients treated by repeated thoracentesis in other series.[14-15]

Thoracotomy

If chest tubes are used for hemopneumothorax, they must be large bore (40-44 F), so that clotting and occlusion do not easily occur. If there is continued bleeding or massive clotted hemothorax, this type of treatment must be abandoned and open thoracotomy utilized instead. Expansion of lung must be achieved rapidly and treatment with tubes discontinued if this does not occur.

Thoracotomy may be indicated for treatment of penetrating chest wounds either immediately or after a short period of observation. Immediate thoracotomy is indicated in patients with penetrating chest wounds and intrathoracic hemorrhage (demonstrated by needle puncture of chest) if: (1) Profound shock shows no response to rapid administration of O-negative blood or other volume expander and the establishment of adequate airway, (2) In precordial wounds no immediate improvement follows pericardiocentesis and volume replacement. Thoracotomy is indicated after a short period devoted to stabilization of the patient who initially responds to resuscitative measures under the following circumstances: (1) X-ray demonstration of massive hemothorax and shifted mediastinum, (2) removal of 1000 ml. or more of blood from chest initially in a patient who continues to demonstrate cardiovascular instability, (3) continued bleeding from chest tubes of 200 ml. or more per hour, (4) with few exceptions, all other precordial wounds, (5) massive air leak and lung collapse indicating tracheal or major bronchial injury, (6) suspected or proven esophageal injury. Modified thoracotomy may also be required occasionally for closure of large chest wall defects. Large foreign bodies, foreign bodies in close proximity to important mediastinal structures, or foreign bodies which cause infection may require thoracotomy for removal. Usually the decision to remove foreign bodies in the thorax does not have to be made on an emergency basis and can be deferred until the patient's general condition is stabilized.

Mortality

The mortality rate of 12.8% of penetrating chest wounds reported here is somewhat higher than that reported in other series.[14,16,17] All patients who reached the hospital have been included, even if they died so rapidly that effective treatment could not be instituted. Had these patients who were moribund on admission been excluded, the mortality rate for penetrating chest wounds in this hospital would be only 2.8 per cent. However, this latter figure represents neither the true risk of these injuries nor the potential for its improvement, since the patients who expire from exsanguination shortly after admission constitute the majority of deaths from penetrating chest wounds in hospitals today. In this series, four of the five deaths were in this category. It is apparent from numerous studies that the mortality rates from all types of injuries, including penetrating chest wounds, are greatest in the first few hours after arrival at the hospital. This means that emergency hospitals must formulate and aggressively utilize plans for resuscitation and initial management of critically injured patients if results are to be improved. During the past six months two patients, both of whom appeared moribund on arrival with massive intrathoracic hemorrhage, were taken directly to the operating room while O-negative blood was being given rapidly. Thoracotomy was carried out, bleeding was arrested, and both survived. It is very doubtful that either would have lived had time been spent to obtain cross-matched blood or in attempts to correct hypovolemia and restore blood pressure to normal prior to operation.

Summary and Conclusions

The treatment of the majority of patients with penetrating chest wounds is fairly satisfactory and the ultimate superiority of chest tubes and suction or repeated thoracentesis as treatment for hemopneumothorax will depend on which of these procedures can be shown to have advantages over the other; but for patients who exsanguinate rapidly, more aggressive treatment with employment of thoracotomy will be necessary if they are to survive.

In a series of 39 penetrating chest wounds seen during a five-year period, five patients died; an over-all mortality rate of 12.8 per cent. Four of these five deaths were due to hemorrhage and occurred within four hours of admission. To improve survival rates in patients with penetrating chest wounds, thoracotomy to arrest hemorrhage will need to be performed more frequently.

For the majority of patients who are not candidates for early thoracotomy, chest tubes and suction are preferable to repeated thoracentesis for treatment of traumatic hemopneumothorax.

The Treatment of Ulcerative Colitis with Hydrocortisone Alcohol Retention Enemas*

- A Topical and Systemic Anti-inflammatory Agent

LLOYD F. SHERMAN, M.D.
Minneapolis, Minnesota

SINCE THE advent of oral and topical steroids, considerable progress has been made in the treatment of idiopathic ulcerative colitis, a disease of unknown etiology. The medical literature records the experiences of a large number of investigators, representative of which is the account of Spencer et al.,[1] who reported 10 years of experience with corticotropin and oral or topical[2] steroids in ulcerative colitis therapy.

In 1956 Truelove[3] pioneered the use of hydrocortisone-free alcohol via rectal drip. He noted rapid symptomatic and sigmoidoscopic improvement in 66 per cent of the patients treated, but biopsy specimens indicated a lag in histologic improvement. This was attributed to a small amount of ethyl alcohol that was used to keep the steroid in solution. On changing to the water-soluble hemisuccinate sodium derivative of hydrocortisone,[4] Truelove obtained normalization of the mucosa that paralleled symptomatic improvement. Subsequent clinical studies led him to recommend combined oral and topical steroid therapy for optimal effect.[5-7] Several others[8-12,19-21] have reported results comparable to those of Truelove; they used hydrocortisone hemisuccinate by rectal drip, as well as hydrocortisone acetate suppositories, depending on the extent of colonic involvement. Matts[8-10] used prednisolone-21-phosphate, and was the first to employ a disposable plastic applicator for ease of self-administration.

Hydrocortisone and its acetate and hemisuccinate esters show varying degrees of absorption when instilled into the distal colon, according to the findings of Nabarro et al.[13]

---

*Cortenema by Rowell Laboratories, Baudette, Minnesota.

These investigators found no detectable absorption with a suspension of hydrocortisone acetate, and only slight absorption with a solution of hydrocortisone hemisuccinate sodium. Hydrocortisone alcohol, on the other hand, was absorbed systemically in amounts up to 83 per cent of the administered dose. Patterson[14] and Schwartz[15] confirmed Nabarro's results with the hydrocortisone esters, but Sampson and Brooke[16] and MacDougall[17] more recently have disputed the earlier work and have claimed significant colonic absorption of hydrocortisone hemisuccinate. The latter studies tend to support Liddle,[18] who reported, in 1956, that 26% of a dose of hydrocortisone acetate (suppositories) is absorbed into the blood stream. There seems to be little doubt that these compounds are absorbed to some extent, but the virtual absence of systemic side effects in extensive clinical use suggests that their absorption from the colon is of a low order.

Whether the desirable clinical results obtained with rectally administered hydrocortisone derivatives in ulcerative colitis are due solely to topical effect or to a combination of topical and systemic effects has not been established. It has been shown, however, that difficult cases respond more favorably to combined topical and oral steroids than to either of these routes individually.[2,6,10,12] Therefore it was our feeling that rectally administered hydrocortisone alcohol should be investigated on the premise that its high rate of absorption might obviate the need for separate oral medication. The advantages of hydrocortisone are its availability and economy, and the fact that its usefulness is well-established in the literature.

Materials and Methods

The preparation used in our investigations is a suspension of hydrocortisone alcohol in saline. Methylcellulose is used as a suspending agent, and it is thought that its emollient properties might add a beneficial effect to the medication by soothing the inflamed mucosa and bringing the active ingredient into more intimate contact with the tissues. The suspension has been used in 60-cc. and 90-cc. quantities. The smaller volume is preferable, because it is better retained and covers an adequate area of the colon. We have used a disposable, collapsible plastic container equipped with a lubricated tip for easy insertion into the rectum. The dosage in every case was 100 mg. of hydrocortisone per dosage unit.

Patients were instructed to carefully instill the suspension at bedtime, lying on their left side with the tip of the container directed toward the sacrum to avoid traumatizing the anterior rectal wall. Patients with severe diarrheas were sedated or given paregoric or a commercial preparation of diphenoxylate and atropine (Lomotil) an hour before instillation of the enema. In some cases, it has proved helpful to tape the buttocks together following instillation to aid retention. The importance of retaining the medication, if only for half an hour, was stressed to the patients.

To date, we have used our preparation in over 40 ulcerative colitis patients, all of whom were intractable to the usual medical management, including salicylazosulfapyridine, oral steroids, bland diet, psychotherapy, etc. All of the patients were from private practice, and the series covered a broad spectrum of severity and extent of involvement. Treatment included one retention enema daily for two to six weeks. In the discussion that follows, 20 patients are included. The remaining cases will be reported on later.

Case Reports

The following three cases serve adequately for the entire group.

Case 1 Male, Age 12

Four-year history of recurring bouts of bloody diarrhea and mucous. Has had five exacerbations with the usual treatment of bland diet, salicylazosulfapyridine oral steroids, and psychotherapy. X-ray evidence of "lead-pipe" left colon. Proctoscopic evidence of friable granular mucosa to 25 cm. that bleeds easily with swabbing (chronic ulcerative colitis with exacerbation). Started hydrocortisone alcohol-retention enemas (Cortenema**) once daily, (h. s.) 7-5-63; clinical improvement in two weeks. Proctoscopic return to normal mucosa in five weeks. No exacerbation for one year. Side effects, "sterism."*

Case 2 Male, Age 49

Three-year history of the passage of blood, mucus, and frequent loose stools, with no remissions. X-ray evidence of "serations" of left colonic mucosa. Proctoscopic picture of "pin-point" ulcerations on a granular friable mucosa to 25 cm. Previously treated with bland diet, Azulfidine, oral steroids, etc. Clinical improvement after one week of daily (h.s.) hydrocortisone alcohol-retention enemas.* Proctoscopic return to normal mucosa in four weeks. "Sterism" and mild acne, but no exacerbations in two years.

---

*See Test Your Word Score, page 627.

Case 3 Male, Age 19

Involvement of entire colon with ulcerative colitis with three-year history. Exploratory laparotomy July 1959, because of suspected carcinoma of the cecum. Colon left intact because disease was thought to be subsiding; however, he developed recurring bouts of ulcerative colitis which did not respond to the usual form of treatment during the next four years. Started on Cortenema retention enemas 9-18-62, developed considerable evidence of "sterism" within three weeks but was clinically improved within the same period of time. Proctoscopically normal except for granularity in six weeks with every-other-day retention enemas; revealed normal mucosa except for "foot tracks" two months later. No unusual side effects. No recurrence: 18 months' follow-up.

Discussion of Results

A review of the twenty patients treated is given in Table 1. It will be noted that the majority of this group had ulcerative involvement of the left colon; three had total colonic involvement. Many had long-standing disease (six months to 11 years). All of the patients had received the usual conservative treatment without avail. Six had also received "nonabsorbable" steroid retention enemas. Except for two cases involving the entire colon, with failure to retain the enemas and with advance to toxic megacolon, highly satisfactory results were obtained in all. Although it is too early to make a final judgement, there are indications that the periods of remission for many of these patients will exceed the expected. Side effects have been negligible. Four patients developed moon face (" sterism") and three developed mild acne.

Total Colonic Involvement

Of the three who had total colonic involvement, two developed toxic megacolon despite intensive treatment, and were colectomized. One colectomy patient (Case 16, a 55-year-old male) died postoperatively with pulmonary embolism after a very "stormy" course; the second (Case 7, a 28-year-old female) survived total colectomy with ileostomy, after a very complicated postoperative convalescence, and is now well-adjusted to her ileostomy. The third patient with total involvement of the colon (Case 3, a 19-year-old male) was explored because of indistinguishability from carcinoma by X-ray, not confirmed, however, at laparotomy. His colon was left intact because the changes were felt to be reversible. This patient did not respond to oral steroids, salicylazosulfa pyridine, or other medical treatment; but after being placed on hydrocortisone retention enemas, he improved symptomatically in three weeks. When next proctoscoped five weeks after institution of therapy, he presented a normal appearing colonic mucosa.

The two colectomized patients were first seen with fulminating disease and could not retain enemas; they further went on to develop toxic megacolon. Most physicians and surgeons who have had experience with ulcerative colitis recognize this possibility and agree that not every patient can be cured by conservative measures, but that topical and systemic steroids are very worthy of trial. Close observation is imperative, so that corrective surgery can be instituted immediately if irreversible deteriorization seems imminent.

Regional Enteritis

Several of the patients treated (for example, Cases 12 and 14) had regional enteritis. Case 12, who had had a subtotal colectomy and ileal resection with an ileoproctostomy, developed recurrent rectal disease that did not react to the usual treatment. He responded promptly and has remained well for over one year after a four-week period of treatment with hydrocortisone alcohol-retention enemas. Case 14 had a total colectomy and repeated small bowel resections for recurrences. Further disease developed with a stricture of the terminal small bowel. Since she had no further small bowel to spare to the surgeon, hydrocortisone alcohol instillations and tamponades soaked

*Salicylazosulfapyridine (Azulfidine)

with hydrocortisone solution were tried. Endoscopic evidence of a relented stricture and a fairly normal mucosal pattern were apparent within four weeks.

Prognostic Guides

The chronicity and extent of disease obviously influences the results of treatment. Patients with rectal and sigmoid involvement or even left colon disease, and those with a short duration of disease, responded more quickly clinically and proctoscopically. However, since this medication has considerable systemic absorption, we are becoming increasingly less reluctant to use it in patients whose entire colon is involved with ulcerative colitis. In these cases, we frequently supplement the retention enemas with oral steroids, such as methylprednisolone.

Strictures and pseudopolyposis are not contraindications to treatment; we have seen both return to a normal mucosal pattern. On questioning, most patients stated that they noted clinical improvement within five to seven days; but since all were private patients and we were somewhat reluctant to incur the cost of repeated proctoscopic examinations, most of them were not re-examined until four to five weeks after treatment was started. Earlier proctoscopic examinations no doubt would have confirmed an earlier return to normal mucosa. This will be confirmed in a subsequent group of twenty patients whose charts are currently being reviewed. This group is very similar to the ones already reported here, except that we have not had to resort to surgery in any of them, and have had only one failure with the hydrocortisone retention enema routine.

In view of our results, there is every reason to believe that hydrocortisone alcohol is absorbed to a greater extent than its hemisuccinate derivative which has been used by the other investigators. The occurrence of mild steroid side effects, as well as the highly favorable clinical results in several difficult cases, suggests considerable absorption of the dose administered (100 mg.). It is entirely possible, also, that an enhanced topical effect is provided by more intimate contact with the tissues during the process of absorption.

We are currently instituting blood-level studies in our private practice and at the Minneapolis Veterans Administration Hospital to ascertain the degree of absorption with our particular formulation. At the same time, radioisotopic venous blood studies are in process at the University of Minnesota with reference to the steroid treatment of factitial* proctitis. It is hoped that both of these investigations will shed light on the unsettled question of hydrocortisone absorption from the colon.

Summary and Conclusions

1. An effective and inexpensive agent for the topical and systemic treatment of ulcerative colitis is discussed. Twenty cases refractory to other conservative measures are described.

2. Location and chronicity are influencing factors in remissions, although involvement of the entire colon and long-standing disease are not contraindications to treatment by this method.

3. Considerable systemic absorption is acknowledged—but we believe this enhances the effectiveness.

4. Objective side effects are few.

5. Although we acknowledge no panacea, until something better is advanced we feel that this treatment is safe, efficacious and worthy of trial in most cases of ulcerative colitis.

WHAT'S YOUR DIAGNOSIS?

A 21-year-old married female was admitted to the hospital with a six-hour history of abdominal pain.

The onset was fairly sudden with pain in the anal area associated with the desire to defecate. Pain was steady with an occasional overlay of crampy pain. An enema, early in the course of the illness, had given relief for an hour or two. The pain then spread to the lower half of the abdomen and gradually to the upper abdomen. When the pain spread to the upper abdomen she experienced some dyspnoea when lying down. Mild nausea was evident, but there was no vomiting.

The past history was essentially noncontributory. The menstrual periods were normal with the last one two weeks previously. There was no known recent infection.

Physical examination revealed no evidence of upper respiratory infection. There was generalized abdominal tenderness, very marked in the lower half of the abdomen, and especially in the lower quadrant of the abdomen. Rebound tenderness was evident in the lower abdomen, but this finding was equivocal in the upper abdomen. No masses were palpable. The pelvic examination was not wholly satisfactory, due to pain and poor cooperation. No masses were identified, but the area of both adnexae was tender with somewhat more tenderness on the left than on the right. The uterus seemed retroverted, and pain was reproduced when the cervix was manipulated.

Temperature was 98.6. Blood pressure 104/60. Pulse 78.

The urine examination was negative for albumin and sugar with one or two red blood cells in a catheterized specimen. Hemoglobin was 13.1. White count was 18,900. Neutrophile 75; lymphocytes 21; bands 4. Chest X ray was negative.

Flat and upright films of the abdomen revealed gas scattered throughout the colon with a small amount of gas in the small bowel. There was no free gas in the peritoneal cavity.

The patient was operated on under the diagnosis of an acute abdomen.

Recommended Dosage of Lomotil Liquid to Control Diarrhea

File:✓ Diarrhea

LOMOTIL®

Age	INITIAL LOMOTIL LIQUID DOSAGE*
3-6 mo.	½ tsp. t.i.d. (3 mg.)
6-12 mo.	½ tsp. q.i.d. (4 mg.)
1-2 yr.	½ tsp. 5 times daily (5 mg.)
2-5 yr.	1 tsp. t.i.d. (6 mg.)
5-8 yr.	1 tsp. q.i.d. (8 mg.)
8-12 yr.	1 tsp. 5 times daily (10 mg.)
Adult	2 tsp. 5 times daily (20 mg.) (or 2 tablets q.i.d.)

*Based on 4 cc. per average teaspoonful.

Note: After diarrhea is controlled the initial dosage can usually be reduced to meet the requirements of the individual patient.

LOMOTIL® TABLETS/LIQUID

Each tablet and each 5 cc. of liquid contains:

diphenoxylate hydrochloride ....2.5 mg.
(Warning: May be habit forming)
atropine sulfate ....0.025 mg.

Precautions

Lomotil is an exempt narcotic preparation of very low addictive potential. Recommended dosages should not be exceeded. Lomotil should be used with caution in patients with impaired liver function and in patients taking addicting drugs or barbiturates.

Cautions and Side Effects

Side effects are relatively uncommon but among those reported are gastrointestinal irritation, sedation, dizziness, cutaneous manifestations, restlessness and insomnia.

Lomotil is a brand of diphenoxylate hydrochloride with atropine sulfate; the subtherapeutic amount of atropine is added to discourage deliberate overdosage.

SEARLE *Research in the Service of Medicine*

at Merck Sharp & Dohme...

understanding... precedes development

The development of chlorothiazide and probenecid were events of major importance, but perhaps even more important for the future was the Renal Research Program by which they were developed. When Merck Sharp & Dohme organized this program in 1943, it was expressing in action some of its basic beliefs about research:

- Many problems connected with renal structure and function were still undefined or unsolved. The Renal Research Program would begin its basic research in some of these problem areas.
- From knowledge thus acquired might come clues to the development of new therapeutic agents of significant value to the physician.

For example, the Renal Research Program put fifteen years into this search before chlorothiazide became available. But because these years had first led to a greater understanding of basic problems, the desired criteria for chlorothiazide existed before the drug was developed.

Along with other research teams at Merck Sharp & Dohme, the Renal Research Program continues to add new understanding of basic problems—understanding which will lead to important new therapeutic agents.

Editorials

The Fifty Year Club

In the month of May each year the Minnesota Medical Association honors those members, who have been in practice half a century, by election to the *Fifty Year Club*. The group this year receiving a lapel pin signifying this honor, will be listed in the June issue together with a short biography. Minnesota Medicine congratulates this distinguished group of physicians upon their achievements.

The qualifications for election to the Minnesota Medical *Fifty Year Club* are simple but somewhat demanding, since most of the members of the class of 1915 are not now present to receive the award. These are the requirements: The physician must have been a member of the Minnesota Medical Association continuously since 1915; he must have completed the preponderant majority of his practice in the state of Minnesota; and he must be alive to receive the award.

That far off year of 1915 was a year of cataclysmic struggle for world power in Europe. In this, the second year of World War I, the outcome of the war was still very much in doubt, but the shores of Minnesota were far from world conflict. One comes across scant reference to the war in the local medical journals of that time: The St. Paul Medical Journal and the Journal Lancet, which combined the Journal of the Minnesota State Medical Association, was the official organ of the North and South Dakota state medical associations. The latter was a semi-monthly publication. Doctor W. H. Condit noted that his long planned visit to Vienna had to be cancelled, and to his surprise he found that he could find good training in obstetrics and gynecology in New York.

The great struggle in this state in 1915 concerned the affiliation between the Mayo Foundation and the Medical School of the University of Minnesota. There can be no question that the proposal signed by George Vincent, President of the University, Elias P. Lyon Dean of the Medical School, James E. Moore representing the Surgical Department, Jennings Litzenberg OB-GYN, and Richard Beard of the Medical Department rocked the state medical society to its foundations. This committee reported: "The immediate development, with a minimum of cost to the University of a graduate school in medicine, which will stand absolutely alone in the sphere of medical education in America as compassed today and will set the type of graduate instruction for the country at large, is an opportunity not to be put by, and one of which leading medical educators throughout the country are taking full account." The affiliation, of course, was established, although the objections of the medical profession were vociferous, and several prominent faculty members of the Medical School resigned their positions.

1915 was the year of the birth of several important medical institutions. William Rodman, President of the JAMA in 1915 started a new examining board which he called the

National Board, although the first examinations were not given until the following year. The Minnesota Dermatological Society was formed at a preliminary meeting held in Minneapolis, October 19, 1915. Officers for the first year were elected as follows:

President — Burnside Foster, M.D., St. Paul.

Vice President — S. E. Sweitzer, M.D., Minneapolis.

Secretary and Treasurer — G. M. Olson, M.D., Minneapolis.

The following is an excerpt from "Emergency Surgery and Country Practice" by M. M. Grove, Journal Lancet, Volume 35, page 35, 1915.

"Case 3 — Dr. O. O. S., aged 59. For the past several years the patient has suffered from periodic attacks of so-called dyspepsia or indigestion. For the past few months he has lived on malted milk and liquids, any solid food except pancakes producing severe pain in the stomach. The patient had partaken of pancakes three times a day for the past week. About 4 o'clock in the afternoon on October 28, I received a telephone call to go at once to the patient's residence. I found him writhing in pain, retching and gagging. The abdomen was tense and rigid. The pulse rapid and weak. Then upon a hurried but careful physical examination concluded that he had a perforation of the stomach due to an ulcer or malignancy, and I was confirmed in my diagnosis by my colleague, Doctor Eagen. I advised operation at once, but as the patient was one of my own competitors I decided on consultation. Under Ether anesthesia I opened the abdomen through a median incision. On opening the abdomen and bringing the stomach into view, we found a perforated gastric ulcer located anteriorly upon the lesser curvature near the pylorus. The stomach contents, consisting of undigested pancakes, malted milk, and water had poured through the opening in large quantities. The ulcer was not excised but was closed over double suture of linen and then covered with omentum. A posterior gastro-enterostomy was performed, and the appendix removed. The patient made an uneventful recovery. Since the operation he has gained his loss in weight and eats anything and everything."

Excerpt — *The Loyalty of Nurses,* ibid, page 129 by Harriet M. Prime, R.N.

"The advice Doctor George Douglas Head gives to the graduating class of the Asbury Hospital seems very good and very elevating to our profession. But I would like to analyze it to show that it is not quite practical. Because we ask for three hours rest out of the 24 and because we ask for a fixed rate of service, Doctor Head says that our loyalty to high ideals is diminished. A nurse cannot do a duty to a patient if she does not have the proper rest. Doctor Head may say that most patients are not in need of constant attention for more than a few days or a week and that a nurse can stand this for that length of time without rest hours."

Anonymous editorial — "In the past few years an effort has been made to transfuse blood from a normal individual to one who is in immediate danger. Two patients received transfusions of 300 cc and 500 cc without untoward symptoms. The blood from the donor is allowed to run through an ordinary cannula into a glass jar containing 5 cc of a 10 per cent solution of sodium citrate. The combined solution is then poured into an ordinary glass funnel which is connected with the cannula to the patient by means of a rubber tube. The whole process can be accomplished in about 5 minutes."

Item — Journal Lancet, page 275. "Doctor Thomas S. Roberts of Minneapolis has been elected professor of Ornithology and assistant curator of the biological museum of the University of Minnesota. Doctor Roberts is probably the best ornithologist in the Northwest. He will probably some day retire from the practice of medicine, and devote his whole time to University work."

The value of the electrocardiogram in the study of the heart by Ernest T. F. Richards and Ralph E. Morris — St. Paul Medical Journal, Volume 37, page 539: "In the more recent years methods of heart examination and the study of its action have received great impetus through the development of the electrocardiograph. What does the association of

SANBORN COMPANY

with

Hewlett-Packard Company

mean to doctors . . . hospitals . . . researchers?

Sanborn Company recently became a division of the Hewlett-Packard Company whose headquarters are in Palo Alto, California. Hewlett-Packard, now in its 25th year, has become one of the world's leading manufacturers of electronic test instruments for government, industry, and research, with plants and sales/service facilities throughout the world. It is still directed by founders Bill Hewlett and Dave Packard and enjoys the widespread respect which their integrity and ingenuity have earned.

SANBORN will now be known as
the
SANBORN DIVISION of HEWLETT-PACKARD.

Sanborn will continue to maintain engineering, manufacturing, sales, and service headquarters in Waltham, Massachusetts. The same intimate knowledge of the instrumentation requirements of the medical profession will continue to guide the management of SANBORN as an H-P Division.

In addition to all that the name SANBORN has meant to doctors over the past 48 years, this new association of SANBORN/HEWLETT-PACKARD means an even stronger organization standing behind every Sanborn instrument and system — stronger in service, facilities, technical knowledge and ability, and in desire to contribute to medical science. Sanborn Division, Hewlett-Packard Company, 175 Wyman Street, Waltham, Mass.

strument of precision, and through its use the study of cardiac disease has become altered and greatly improved, for the graphic records formed are authentic documents — proofs indeed — of normal or perverted cardiac action."

1915 was a great year for focal infections. Innumerable tonsils were separated from their beds, and dental laboratories were kept busy making plates for patients whose general problems were ascribed to local disease.

This writer, living in the north side of Minneapolis at that time, attending Harrison School across the street from fire engine company No. 16, can recall across the bridge of 50 years the excitement of the fire alarm, the four dappled white horses hitched up in seconds to the steamer and the fine sight of the polished brass and red chariot with the dappled horses, sparks flying from their hoofs and red flames showing in the fire box below the steam generator. 1915 is a year of splendid memories.

Minneapolis, Minnesota

Hypertension and Renal Artery Stenosis

During the past 10 years, particular attention has been paid to surgical correction of occlusive lesions of the renal arteries in patients with diastolic hypertension. It soon became apparent that renal artery atherosclerosis was quite common among normotensive persons. Indeed, in an unselected necropsy series, we observed[1] moderate or severe narrowing of the renal arteries in 49 per cent of 256 normotensive cases and 77 per cent of 39 hypertensive cases. Clearly, atheromatous narrowing of the renal arteries is not necessarily related causally to associated hypertension. How can we distinguish those cases of hypertension in which the renal artery stenosis is an associated finding from those in which the stenosis causes (or seriously aggravates) the hypertension?

Obstructive lesions of the renal arteries, of diverse cause, may result in altered renal hemodynamics, in changes in the renal handling of solute and water by the individual kidneys, and in the elaboration of pressor substances. The interrelationships between these effects and the production of chronic hypertension in man are not clearly established. However, our studies have indicated that, when there is stenosis of the main renal artery, excellent surgical results may be anticipated if characteristic ipsilateral functional abnormalities can be demonstrated — in particular, the excessive reabsorption of sodium and water and the elaboration of urine having less sodium but more total solute than found in the urine from the contralateral kidney.[2,3] Although renal arteriography and separated renal function studies are the procedures of choice for reliable diagnosis of functionally significant renovascular lesions, operative cost and risk prevent their use in screening large numbers of hypertensive patients.

The procedures which we have found to be of great value in screening include excretory urography (particularly when the technic is modified to include early films) and isotope renography. These tests are safe and easy to perform. Because there is no single uniformly reliable screening test, we carry out both urography and renography in patients suspected to have a renovascular lesion. Very few false-negative results have been encountered. If the tests are positive and if the patient is otherwise a favorable candidate for surgical treatment, further evaluation is carried out by arteriography and separate function studies before operation is advised.[3]

Measurement of pressure gradients may be of value in predicting success in some renovascular lesions, but, generally, these can only be determined at laparotomy, particularly when the stenotic lesions are more distally located. On the other hand, the

ɪmposition: Each tablet contains chlorthalidone, mg., and reserpine, 0.25 mg.
ɪntraindications: History of mental depression, persensitivity, and most cases of severe renal hepatic diseases.
ɜrning: Discontinue 2 weeks before general esthesia, 1 week before electroshock therapy, d if depression or peptic ulcer occurs.
ɜcautions: Reduce dosage of concomitant anti-pertensive agents by one-half. Discontinue if BUN rises or liver dysfunction is aggravated. ɜctrolyte imbalance and potassium depletion ɪy occur; take particular care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side Effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.

Average Dosage: One tablet daily with breakfast.
Availability: Bottles of 100 and 1000 tablets.

*Chupkovich, V.; Finnerty, F. A., Jr., and Kakaviatos, N.: The value of chlorthalidone plus reserpine in moderately severe and severe hypertension: A two year study. Presented at the 7th Inter-American Congress of Cardiology, Montreal, June 14–19, 1964.

significance of a gradient (or its absence) may be greatly reduced because of technical reasons — for example, in lesions of small accessory arteries or with extensive fibromuscular dysplasia.[4]

Another approach to this problem of stenosis and high blood pressure has been based on the possibility of a humoral mechanism. Tigerstedt and Bergman,[5] in 1898, observed pressor effects from renal venous blood and proposed the term "renin." The wealth of subsequent researches into renin-angiotensin-aldosterone mechanisms has helped to explain many experimental types of hypertension, but it has been so diffcult to measure these substances that there has been little practical clinical application of these findings.[6] Indirect assessment of the humoral mechanism, by the measurement of the pressor response to infusion of exogenous angiotensin, has been shown recently to be of clinical value in *carefully selected* instances; patients with functionally significant renovascular hypertension were more resistant to the pressor effects of angiotensin when they did not have malignant hypertension, salt retention states, and depletion of plasma volume.[7] In an earlier study, the angiotensin skin test proved to be a nonspecific reaction.[8] It seems improbable that so complicated a syndrome as renal hypertension will be explainable on the basis of a single mechanism or through the action of a single substance. More likely, angiotensin is but one of many important and interrelated components of a vast but normally equilibrated system whose basic purpose is to provide for the constantly changing requirements of tissue perfusion.[9]

Our first 62 surgically treated patients were selected on the basis of both functional and anatomic criteria, and 40 of them are normotensive six months to five years after operation, 12 are normotensive by the use of only mild to moderately potent antihypertensive agents, and 10 are not improved. Those patients who did not respond well to surgical treatment generally had lesions which could not be satisfactorily corrected from a technical standpoint or did not have clear evidence of a functionally significant lesion.[3]

Although recent researches in the humoral mechanisms of this type of hypertension hold forth the promise of more specific guides to enable the clinician to recognize more easily those patients with surgically reversible renovascular hypertension, our experience indicates that, for the present, both renal arteriography and measurement of function of the individual kidneys are essential to determine the relationship of renal artery stenosis to associated hypertension. In spite of impressive research progress, the management of these patients remains based on enlightened empiricism.

Depend on low-cost, low-dosage Prolixin — once-a-day

Prolixin is a dependable tranquilizer that provides your patient with low cost therapy. No other tranquilizer costs less. Safe and convenient for office use—Prolixin in a single daily dose provides prolonged and sustained action. Markedly low in toxicity and virtually free from usual sedative effects —Prolixin is indicated for patients who must be alert. Clinical experience indicates fluphenazine hydrochloride is especially effective in controlling the symptoms of anxiety and tension complicating somatic disorders such as premenstrual tension, menopause, or hypertension—also useful for anxiety and tension due to environmental or emotional stress. When you prescribe Prolixin you offer your patient effective tranquilization that is low in cost, low in dosage and low in sedative activity.

THE SQUIBB TRANQUILIZER

WHEN TRANQUILIZATION WITHOUT SEDATION IS DESIRABLE, TRY PROLIXIN®

SQUIBB FLUPHENAZINE HYDROCHLORIDE

SIDE EFFECTS, PRECAUTIONS, CONTRAINDICATIONS: As used for anxiety and tension, side effects are unlikely. Reversible extrapyramidal reactions may develop occasionally. In higher doses for psychotic disorders, patients may experience excessive drowsiness, visual blurring, dizziness, insomnia (rare), allergic skin reactions, nausea, anorexia, salivation, edema, perspiration, dry mouth, polyuria, hypotension. Jaundice has been exceedingly rare. Photo-sensitivity has not been reported. Blood dyscrasias occur with phenothiazines; routine blood counts are recommended. If symptoms of upper respiratory infection occur, discontinue the drug and institute appropriate treatment. Do not use epinephrine for hypotension which may appear in patients on large doses undergoing surgery. Effects of atropine may be potentiated. Do not use with high doses of hypnotics or in patients with subcortical brain damage. Use cautiously in convulsive disorders.

AVAILABLE: 1 mg. tablets. Bottles of 50 and 500.

Smoking and Health

THE ARTICLE "Smoking Habits and Disease in Minnesota," appearing in the January issue of MINNESOTA MEDICINE,* serves as one more reminder that cigarette smoking is a serious health hazard. The responsible physician should be aware of this fact and should act accordingly. As Dr. Luther Terry, Surgeon General of the U. S. Public Health Service, has stated, "None of us should be misled by the half-truth that we need more research before we take action. We need more research . . . but the research is to learn how cigarette smoking produces lung cancer, bronchitis and other diseases, not whether it produces them. On that part of the question, the facts are now in." Indeed, they are!

Certainly, the physician has an obligation to educate the public, and the youth in particular, to the dangers of continued cigarette smoking. We should, by word and example, encourage the heavy smoker to stop and discourage the nonsmoker from taking up the habit.

In addition, the physician has a definite responsibility to those who smoke heavily but who either cannot or will not change their smoking habits. These are the persons in whom there is a distinctly increased risk of lung cancer, bronchitis, emphysema, and heart disease. For example, it is known that in the man who habitually smokes two packages of cigarettes a day, the chance that lung cancer will develop is approximately one in 10.

The chronic cigarette smoker who continues the habit should be advised to have frequent examinations, at least as often as every six months. The examination should include a roentgenogram of the thorax, as well as whatever additional procedures are judged appropriate. In this way earlier diagnosis and, hopefully, more effective treatment of diseases related to smoking may be possible.

Robert S. Fontana, M.D.
Rochester, Minnesota

Finnagle's Laws

FINNAGLE IS most often remembered for his description of the peculiar properties of the Finnagle factor. In its simplest form the Finnagle factor is expressed as that factor plus or minus which, times which, or divided by which the wrong answer gives the right answer. Application of one or more of the four operations, singularly or in succession will always yield the correct answer to any problem. This factor has been used most often in sophisticated scientific work where the answer to a problem has been less important than the recovery of consistent data.

Finnagle's First Law

"If anything can go wrong it will." A recent study of this law has shown that no continuous function could possibly account for things going wrong. It was apparent, therefore, that such characteristics were quantized in accordance with Planck's laws of quantum mechanics. This work has lead to the restatement called the quantization provision or Murphy's law, which is, everything goes wrong all at once. A further application

Continued

to help relieve pain in common anorectal disorders

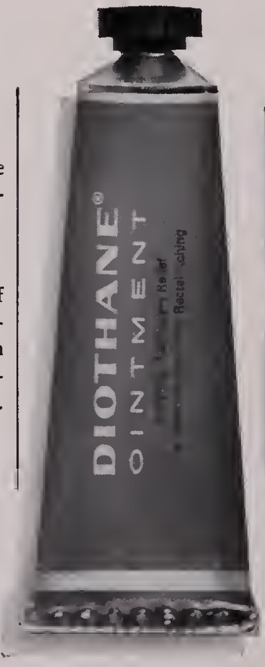
"non-caine" Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form...both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.



CHILL
↑PULL APART↑

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

Merrell

THE WM. S. MERRELL COMPANY
Division of Richardson-Merrell Inc.
Cincinnati, Ohio 45215/Weston, Ontario

has been called the Step Ahead principle which is a qualitative measurement of the increasing complexity of the work, the more that is accomplished. The statement of this principle is called Stock-Mayer's theorem after the man who first stated it in the following form- "If it looks easy it's tough; if it looks tough it's impossible."

Finnagle's Second Law

"Matter will be damaged in direct proportion to its value." Strang has attempted to quantitate this law in terms of Strang's misery units. These have been irreverently known as UGS. He has been having trouble though, and so far the base units have not been clearly and inevocably defined. In his studies he refers to the mechanical application of the law: a car that runs smoothly until miles from any garage; the appliance that operates perfectly only when a repairman is there; and the immediate breakdown of anything a day after the manufacturer's guarantee runs out. He also referred to the climatological phenomena in this study. Here we have rainfall immediately after washing of the car, or a cold wave as soon as the furnaces are closed down for the winter. However, Strang and Springle's extension of this law into gravitation have not been completely accepted. Their statement that things fall at right angles is completely invariant with the well known fact that toast always falls buttered side down. These are, however, only a small smattering of the applications of the law.

Finnagle's Third Law

"No matter what happens, somebody somewhere will tell you I told you so." So far no direct applications of this law have been discovered.

Finnagle's Fourth Law

"Even if it is impossible to incorrectly assemble a part, still a way will be found to do it wrong." Thus far this law has been found to be immutable.

Finnagle's Fifth Law

"Whenever a system becomes completely defined, something is discovered which either abolishes the system or expands it beyond recognition." The basis of this law has been present in folklore for countless centuries. It has provided both an optimistic outlook and a pessimistic outlook. I refer to the two sayings, "There is always room for improvement," and "No matter what you do it won't make any difference."

It is to be expected that careful study of Finnagle's laws of the universal perversity of matter will lead to the discovery of many corollaries and applications which will be useful in basic research, clinical medicine, and the enjoyment of everyday life.

These observations have been collected over many years from multiple sources — writings, word of mouth, and personal observations — so that it is not possible to give accurate credit to the original contributors. The history of the formulation of these important laws would also be a vital field for study.

Progress in Cervical Cytology

THE FEBRUARY issue of Minnesota Medicine* contains an article reviewing the results of a cervical cytology survey conducted by the Cancer Control Section of the Minnesota Department of Health with the co-operation of the Cancer Committee of the Minnesota State Medical Association and the Cytology Committee of the Minnesota Division, American Cancer Society. A total of 1,835 questionnaires were completed and returned by nearly half the licensed physicians in Minnesota. Of the responders, 1,684 stated that they examine the female pelvis, and 1,223 or 72.6% stated that they make routine cancer smear tests of the vaginal or cervical secretion. According to type of practice, 93.1%

Summary of contraindications, cautions and side effects: Do not use in patients with glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal obstruction, or bladder neck obstruction. Use with caution in the presence of hypertension, hyperthyroidism, or coronary artery disease. Drowsiness; excessive dryness of nose, throat or mouth; nervousness or insomnia may occur on rare occasions but are usually mild and transitory.

Before prescribing, see SK&F product Prescribing Information.

Smith Kline & French Laboratories SK&F

of the obstetricians and gynecologists, 89.8% of internists and 67.0% of general practitioners reported taking smears routinely. Over 80% of all groups preferred to take the smear test at yearly intervals, while only 64.3% advised taking the first smear test before the age of 30 years. A surprising finding was that only 34.8% of responders routinely made smear tests during pregnancy.

Many studies have shown that severe dysplasia and occasionally preinvasive or invasive carcinoma of the cervical epithelium occurs during the second and third decades of life. Young women, pregnant or not, deserve the protection of the cytology smear test as much as their older sisters. The premise that smears are inaccurate during pregnancy has been disproved. Some physicians fear that the finding of a positive smear will lead to the need for investigative procedures that may imperil present or future pregnancies. This premise too has been disproved by large series of cone biopsies performed during pregnancy with small risk of abortion. The cone should be performed after the third month of pregnancy and should be conservative in size.

A second and as yet unpublished survey was made of thirteen hospital cancer registries in the state of Minnesota during 1963 to determine the effect of the cytology smear test on the incidence of preinvasive and invasive cancer of the cervix. The data was obtained by the Cancer Control Section of the Minnesota Department of Health and was compiled by the writer. This survey which included the years 1958 through 1963 showed a sharp rise in the number of diagnoses of carcinoma in situ from 65 in 1958 to 182 in 1961. A slight decline then occurred to 173 in 1962 and 153 in 1963. During the same years the number of cases of invasive carcinoma of the cervix did not change significantly.

The failure of the Minnesota registry study to show a decrease in incidence of invasive carcinoma of the cervix is in contrast to the findings of studies in both British Columbia and Shelby County, Tennessee, where intensive population screening programs have been in process for over a decade. The British Columbia study reported a drop of 45% in the incidence of invasive carcinoma of the cervix, and the Shelby County study reported an even greater drop. In both these studies the incidence of carcinoma in situ levelled off to 46 and 45 per 100,000 women respectively. Comparison of the incidence curves of these two studies with the Minnesota registry study suggests that in Minnesota the use of cervical cytology hasn't existed long enough to show the expected decline in the number of diagnoses of invasive carcinoma of the cervix.

The ultimate value of the smear test must be judged by its ability to effect a marked drop in mortality rate for carcinoma of the cervix. The Cancer Control Officer for the Minnesota Department of Health, Dr. J. J. McCullough, obtained the following figures: for the United States a decline from 10.8 per 100,000 females in 1953 to 9.0 in 1962. In Minnesota the rates have dropped from 7.2 in 1955 to 5.4 in 1963. The decline for the whole country was 16.6% and that for Minnesota was 25%. By comparison the Shelby County death rate for white females dropped 59% from a peak of 22 per 100,00 in 1953 to 9 per 100,000 in 1961.

From the above it is apparent that Minnesota shares with other regions the great impact made on the early diagnosis of carcinoma of the cervix uteri by widespread use of cervical cytology. However, the results of these studies show little cause for complacency among those agencies charged with the responsibility for public and professional education in the area of cancer detection.

The Editor's Soliloquy

A Couple of Beers

In the usual circumstance a couple is two, but in beer a couple has no numerical equivalent. It is not one and certainly not two, for the habitue whose breath discloses the indulgence would happily admit the specific one or two when apprehended, in order to absolve himself of a possible accusation of intoxication; the nonspecific "couple of beers," he opines, leaves him clear of any wrongdoing. If he is dragooned by an inquisitive officer to three or more, his memory fails him as he glibly absolves himself of any such penury as counting beers with a friend. Certainly no accusing officer would be so insular as to incriminate a man for drinking, after only a couple of beers. Not even the drunkometer would give more than a trace of alcohol from a couple of beers, but in the state of Connecticut a man* who drank "a minute amount" was found guilty of driving while intoxicated. When he was put in the cell, he pounded on the bars, tore his blanket in strips, and threatened to hang himself. He had failed the usual sobriety test. The following day he was removed to a hospital where a sympathetic psychiatrist examined him and subsequently testified that the driver's condition at the time of arrest was one of pathological intoxication, which probably could be produced by drinking a minute amount of alcohol, and that the alcohol could not be considered a causative agent but a catalyst, without which such a reaction could not occur.

The law did not distinguish between alcohol as a causative agent and as a catalyst, and the jury found that the driver was so affected by the "minute amount" of alcohol as to appreciably impair his ability to drive.

There was a strong odor of alcohol on his breath, but he admitted drinking only a couple of beers. — Carl O. Rice, M.D.

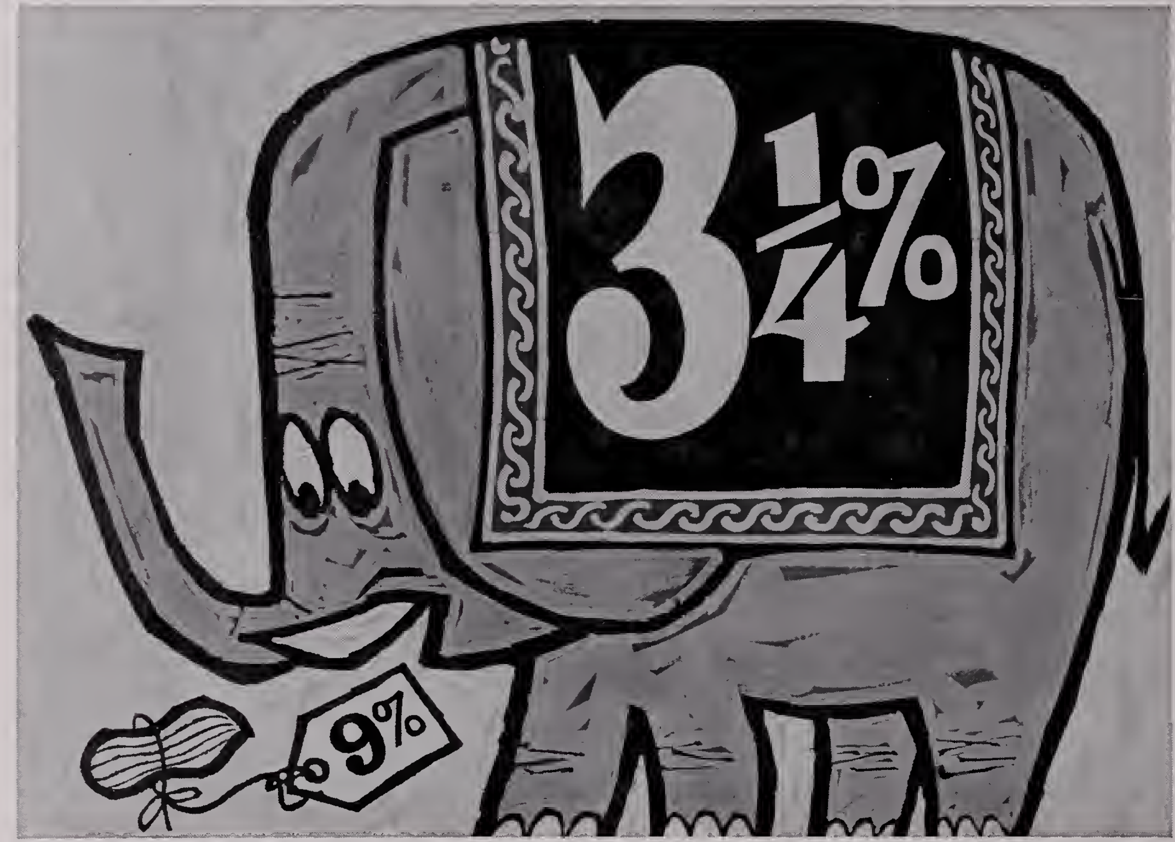
Hiccough

Child's Definition: Something in my mouth makes my head shake and say "hic."
— C.McC

Riddle: When is 3¼% larger than 9%?



Answer! When it represents *keepable* income from tax-free municipal bonds! A 9% yield from ordinary stocks may seem like a nice profit. But, it's really small peanuts, if you're in a high income bracket. Reason? Federal and state income taxes can take a huge amount of that profit away. Not so with *tax-free* municipal bonds! They allow you more "keepable" income . . . more big peanuts to salt away in your trunk! First National Bank offers a large selection of these bonds. Sound good? Then mail the coupon below for our free booklet "The Story Behind Municipal Bonds," as well as our handy "Tax Exempt Versus Taxable Income Table." Both give you vital information that can save you money. Or call our Investment Department (221-9463). So make like an elephant—don't forget—tax-free bonds can give you more *keepable* income!

MINNESOTA MEDICINE

HONOR AWARD

Minnesota Medicine Medical Writing Awards, 1965

It is the pleasure of the Board of Editors to announce the winners of the fourth annual Minnesota Medicine Medical Writing Awards chosen from articles published in MINNESOTA MEDICINE during the year of 1964.

The first place plaque is to be awarded to Dr. Robert L. Strom of the Hennepin County General Hospital; Dr. Wendell H. Hall of the Veterans Administration Hospital and Frances Casey, B.A. of Minneapolis. Their article "Coccidioidomycosis — A Minnesota Experience" appeared in the October issue of MINNESOTA MEDICINE, page 1189. The presentation will take place during the annual meeting of the Minnesota State Medical Association in Minneapolis at the New Members, County Officers and Delegates Dinner on Sunday, May 16th.

Certificates for excellence in medical writing will be awarded to the authors listed on the next page together with the titles of their articles which were felt to be particularly outstanding by the Board of Editors.

PLANNING TO SUBMIT A MANUSCRIPT

HOW TO SUCCEED WITH FAILURES

MANY SULFONYLUREA FAILURES SUCCESSFULLY TREATED WITH

tablets 25 mg. timed-disintegration capsules 50 mg.

DBI® OR DBI-TD

BRAND OF **PHENFORMIN HCl**

IN COMBINED THERAPY

In a 7½-year study of 115 patients treated with oral sulfonylurea drugs, Beaser[1] found that nearly one-half (54) were failures—either primary or secondary. Addition of DBI to the sulfonylurea reversed oral treatment failures in 42 cases. This combined therapy "practically doubled the longevity of treatment possible with oral drugs." Other investigators also report on combined therapy:

> ..."In certain persons with maturity-onset type of diabetes in whom treatment with a sulfonylurea agent does not yield maximal success, the addition of phenformin [DBI] to the treatment program may result in strikingly improved results."[2]
>
> ...DBI is "often useful in augmenting an incomplete response to one of the sulfonylurea drugs."[3]
>
> "...patients who are sulfonylurea failures may respond effectively to the combined therapy [with DBI]."[4]

Dosage: 1 to 3 DBI-TD capsules daily, or 1 to 6 DBI tablets in divided doses with meals. **Side Effects:** Gastrointestinal, occurring more often at higher dosage levels, abate promptly upon dosage reduction or temporary withdrawal. **Precautions:** Occasionally an insulin-dependent patient will show "starvation" ketosis (acetonuria without hyperglycemia) which must be differentiated from "insulin-lack" ketosis which is accompanied by acidosis, and treated accordingly. Lactic acidosis has been reported in nondiabetics and diabetics treated with insulin, with diet, and with DBI. Question has arisen regarding possible contribution of DBI to lactic acidosis in patients with renal impairment and azotemia and also those with severe hypotension secondary to myocardial or bowel infarction. Periodic B. U. N. determinations should be made when DBI is administered in the presence of chronic renal disease. DBI should not be used when there is significant azotemia. Any cardiovascular lesion that could result in severe or sustained hypotension, which may itself lead to development of lactic acidosis, should be considered cause for immediate discontinuation of DBI at least until normal blood pressure has been restored and is maintained without vasopressors. Should lactic acidosis occur from any cause, vigorous attempts should be made to correct circulatory collapse, tissue hypoxia, and pH. **Contraindications:** Severe hepatic disease, renal disease with uremia, cardiovascular collapse. Not recommended without insulin in acute complications of diabetes (metabolic acidosis, coma, severe infections, gangrene, surgery). **Pregnancy Warning:** *During pregnancy, until safety is proved, use of DBI, like other oral hypoglycemic drugs, is to be avoided.*

Bronchoscopic Irrigation

QUESTION: What is the nature of the low-grade infection that requires bronchoscopic irrigation?

ANSWER: Persistent, relatively nonproductive bronchitis requires bronchoscopic irrigation. This applies particularly to the bronchitis associated with a low-grade fever under 100 degress, pressure or mild pain in the anterior chest, and slight dyspnoea or unusual tiredness on exertion, which persists for weeks or months after an acute respiratory infection has subsided. This type of bronchial congestion occurs especially, but not exclusively, in patients with some pulmonary emphysema.

J. Karl Poppe, M.D.
Portland, Oregon

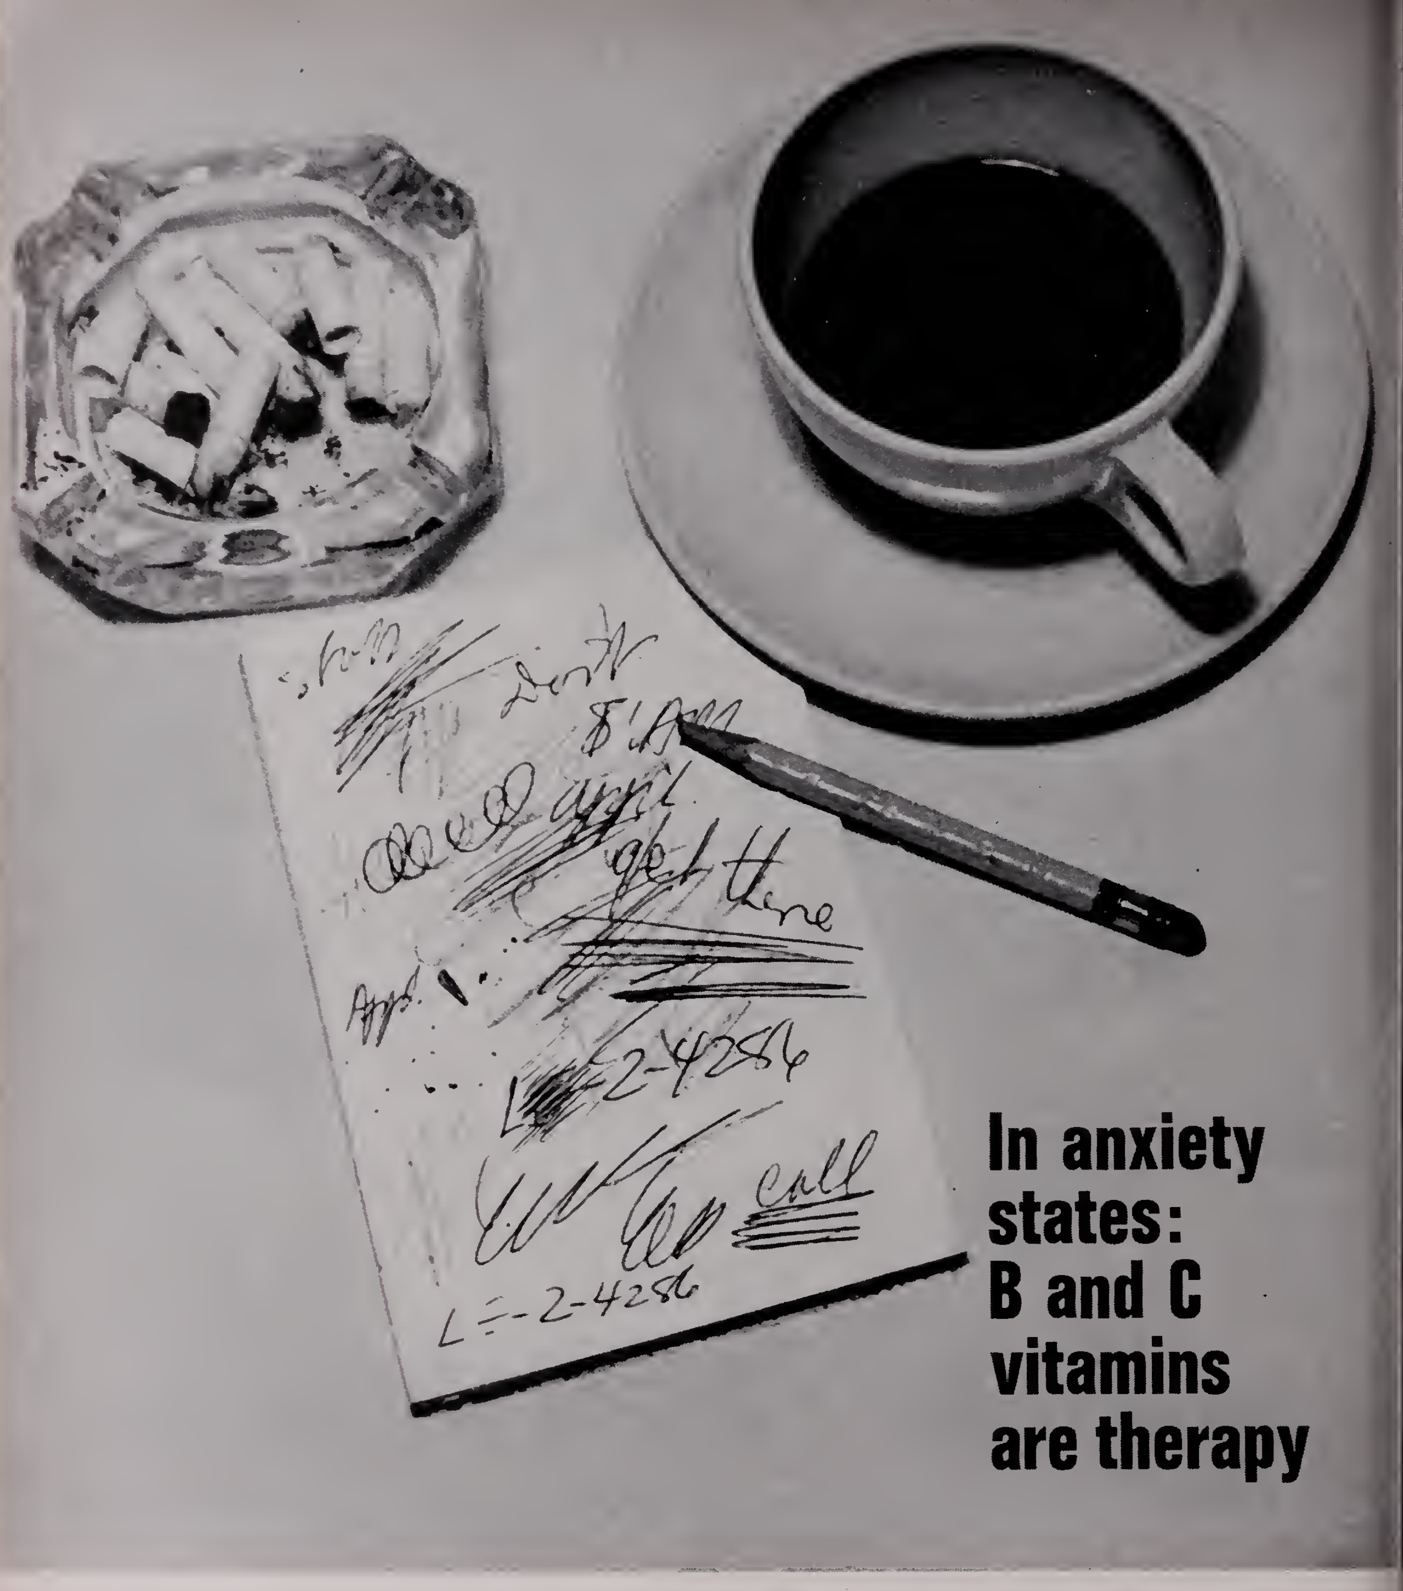
Mushroom Poisoning

QUESTION: I understand most cases of mushroom poisoning are caused by the fungi Amanita muscaria and Amanita phalloides. Is there any difference between the poisoning caused by the two species?

ANSWER: Poisoning by ingestion of Amanita muscaria is due to a parasympathomimetic agent, muscarine, with rapid onset of symptoms (minutes to two hours). Principal symptoms with this type of poisoning are lacrimation, miosis, salivation, sweating, abdominal cramps, diarrhea, vomiting, circulatory failure, coma, and convulsions. Atropine is the specific agent used to antagonize the effects of the muscarine.

Ingestion of Amanita phalloides results in poisoning created by the effects of phalloidin and other toxins in the fungus. A delayed type of intoxication (six to fifteen hours) results from these agents. In addition to the gastrointestinal symptoms, which are similar to those caused by muscarine, liver damage and renal shutdown may result. Circulatory failure and coma generally occur within about seven days. Supportive therapy particularly in the administration of protein is felt to be helpful in preventing liver damage due to phalloidin.

Medicines are nothing in themselves, if not properly used, but the very hands of the gods, if employed with reason and prudence. — Herophilus B.C. 300



In anxiety states: B and C vitamins are therapy

Stress formula vitamins are an important supportive measure in maintaining the nutritional status of the emotionally disturbed patient. With STRESSCAPS, B and C vitamins are present in therapeutic amounts to meet increased metabolic demands. Patients with anxiety, and many others undergoing physiologic stress, may benefit from vitamin therapy with STRESSCAPS.

Each capsule contains:

Vitamin B_1 (as Thiamine Mononitrate)	10 mg.
Vitamin B_2 (Riboflavin)	10 mg.
Niacinamide	100 mg.
Vitamin C (Ascorbic Acid)	300 mg.
Vitamin B_6 (Pyridoxine HCl)	2 mg.
Vitamin B_{12} Crystalline	4 mcgm.
Calcium Pantothenate	20 mg.

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

Fracture–Trauma Conference

Penetrating Abdominal Wound with Aortic Perforation

Treatment of abdominal gunshot wounds has become fairly well standardized since World War II. The principles of obligatory exploration, resection or repair of damaged small bowel, and proximal colostomy or exteriorization of damaged large bowel are well defined.[1] Early definitive treatment in civilian hospitals in peacetime, coupled with less severe injury as produced by small-bore relatively low-velocity missiles, has led some surgeons to recommend primary closure of certain of these colon defects.

One of the major advances made possible by the experience gained during the Korean War was the dictum of repair, when feasible, of important vascular structures.

The patient described in the following interesting case history recovered because of the awareness of these principles, plus rapid transfer from the scene of the accident to a major hospital facility, the 24-hour a day coverage at the hospital by a well trained resident staff, and the knowledge gained from experience with cardiovascular surgical techniques.

Case

A 30-year-old male was brought into the Hennepin County General Hospital on February 5, 1964, unresponsive and with no obtainable blood pressure. He was alleged to have shot himself in the abdomen with his own .22 caliber pistol. He was taken immediately to the emergency treatment room where a cutdown was quickly performed.

A unit of plasma was rapidly given, followed by noncrossmatched O negative blood from the blood bank. His blood pressure became detectable and rose within a few minutes to 110/60. A Foley catheter was placed in his bladder and a nasogastric tube into his stomach. His urine was clear, indicating that the bullet had probably not traversed the genitourinary tract, but the return from his nasogastric tube was bloody. The wound of entry was in the left upper quadrant and there was no wound of exit. Auscultation of his heart and lungs revealed no abnormality. A portable X ray of the abdomen revealed the bullet to be superimposed over the L2-L3 vertebral interspace.

He was taken to the operating room promptly and under a general anesthetic an exploration of his abdomen was performed. It was discovered that the bullet had passed through the stomach and that there was a large hematoma in the mesentery of the colon and small bowel. The posterior peritoneum overlying a large retroperitoneal hematoma was incised and as the clot was removed, a brisk hemorrhage ensued, coming from the abdominal aorta just proximal to the take-off of the inferior mesenteric artery. Digital pressure and Satinski clamps were used to control the hemorrhage. At this point it could be seen that the bullet had passed through the body of the pancreas, then through

Continued

the anterior and posterior wall of the abdominal aorta, lodging in the vertebral column.

The aortic perforations were closed with running 4-0 vascular silk, and after securing complete hemostasis a Penrose drain was placed down to the pancreas. The perforations in the stomach were closed and after careful examination of the large and small bowel, the abdomen was closed. The patient had been given 6500 cc. of blood.

Postoperatively there was a significant amount of pancreatic drainage through the stab wound, but this gradually subsided and he recovered to be sent to the Psychiatric Ward. He was discharged from the hospital on March 7, 1964, with no apparent residua from the bullet lodged in his spine.

Discussion

This case represents only a few of the many problems that may arise secondary to a gunshot wound of the abdomen. It is, however, particularly interesting from the standpoint of abdominal aortic perforation.

A free perforation of the lower aorta or major iliac vessels would almost certainly be lethal over the time period that elapsed from the patient's point of injury until hemostasis was achieved at surgery. In this case, however, the bullet passed through the stomach and pancreas, leaving intact the posterior peritoneum; this helped contain the hemorrhage enough so that a sufficient circulating blood volume was maintained to support life. Also, this was a small-caliber low-velocity bullet, producing two clean perforations.

It should be emphasized that if such a perforation is suspected clinically, and if the patient's vital signs give evidence of a continuing deficit in circulating blood in spite of plasma, plasma substitutes, and blood replacement, then preliminary tests should be waived and the patient taken immediately to the operating room for exploration.

Closure of the perforations with running silk sutures attenuated the diameter of the aorta to a degree. However, this seemed preferable to the placement of a patch, which we felt would be less able to withstand the effects of free pancreatic juice than would the normal aortic wall.

In gunshot wounds of the abdominal cavity, it is important to repair, remove, or drain all involved organs. Consequently the stomach perforations were closed and the pancreas drained. In this instance the postoperative pancreatic drainage did not complicate the patient's course, because an adequate cutaneous exit had been provided in advance.

Tumor Conference

Common Duct Tumor Mimicking Stone

Cholangiography, preoperative, operative, and postoperative, is an invaluable adjunct to the study and treatment of biliary tract disease. A high degree of accuracy in the interpretation of these roentgenograms has been achieved.[1] But it must be emphasized that errors in interpretation do occur, and clinical judgement and repeated, careful re-examination are often necessary in arriving at a diagnosis.[1,2]

Cholangiograms may fail to show stones or tumors when too dense a contrast media is used to fill large duct systems, or when poor films are accepted for interpretation. Air bubbles or spasm of the sphincter may simulate stones or tumor. Enlarged lymph nodes may produce apparent intraluminal defects indistinguishable from stones.[3]

An unusual problem of differential diagnosis of stone and tumors is illustrated in this case.

Case History

A 44-year-old man was admitted to the hospital on May 2, 1961, complaining of severe headaches, nervousness, and tremor of the hands. He also said that for the past five or six months he had had occasional abdominal cramps that would come on after meals, last for five or ten minutes, and then be relieved by drinking carbonated beverages. These cramps were occasionally severe enough to cause him to break out in a cold sweat. The pain radiated over the entire abdomen. Onions, cucumbers, radishes, and occasionally coffee would initiate an attack. Fatty foods did not cause any particular difficulty.

He had been operated on for appendicitis in 1950 and for an inguinal hernia in 1956. Six or eight weeks prior to admission he noticed that his stools resembled tar for a period of several days.

Physical and Laboratory Findings

The physical examination was noncontributory, except that on abdominal examination a slightly tender mass could be palpated in the right upper quadrant. The rest of the abdominal examination was normal. Routine blood, urine, and serological examinations were also normal. One-minute bilirubin was reported as 0.10 mg. and total bilirubin 0.70 mg. per 100 cc. of serum.

His chest film was also reported as normal. X-ray examinations of the abdomen showed a large shadow in the right quadrant resembling a hydrops of the gallbladder. No gallbladder shadow could be seen on the cholecystogram. Studies of the upper and lower gastrointestinal tract and the urinary tract were normal

Continued

Operative Findings

He was brought to surgery and a hugely distended gallbladder found and removed. The common duct was dilated and opened; three small fragments of stone were found and removed. A 4-millimeter probe was passed through the sphincter of Oddi into the duodenum, a T-tube was inserted, and a cholangiogram was done. No defects were seen on the films; and though no dye was seen in the duodenum, the duct was considered patent, and the abdomen was closed.

The pathologist reported that the gallbladder was ulcerated and dilated, with a hemorrhagic infiltration of the wall. The largest stone measured two millimeters in diameter.

Progress

The patient had an uneventful postoperative course. A T-tube cholangiogram was done one week after surgery. The common duct was dilated, and there was a definite narrowing of the distal portion of the duct, which the radiologist thought might be due to a nonopaque stone or a stricture. Dye entered the duodenum readily.

It was possible to clamp the T-tube without causing the patient any distress. He was discharged from the hospital twelve days after surgery and followed with monthly cholangiograms, which consistently showed a dilated common duct proximal to a "ring-like" defect in the distal portion of the duct. It was the impression of several radiologists that the findings were those of gallstone obstruction of the distal common duct.

Six months later he was admitted to St. Barnabas Hospital for choledochotomy. On the preoperative T-tube cholangiogram a ringlike defect was seen in the distal portion of the common duct. Because it appeared that the dye completely encircled the defect (Figure No. 1), the defect was thought to be a radiolucent stone.

The man was again brought to surgery and the abdomen opened through the previous subcostal incision. After freeing the adhesions the duodenum was mobilized, but no stone could be palpated. The T-tube tract was cut off flush with the common duct and readily passed through the ampulla

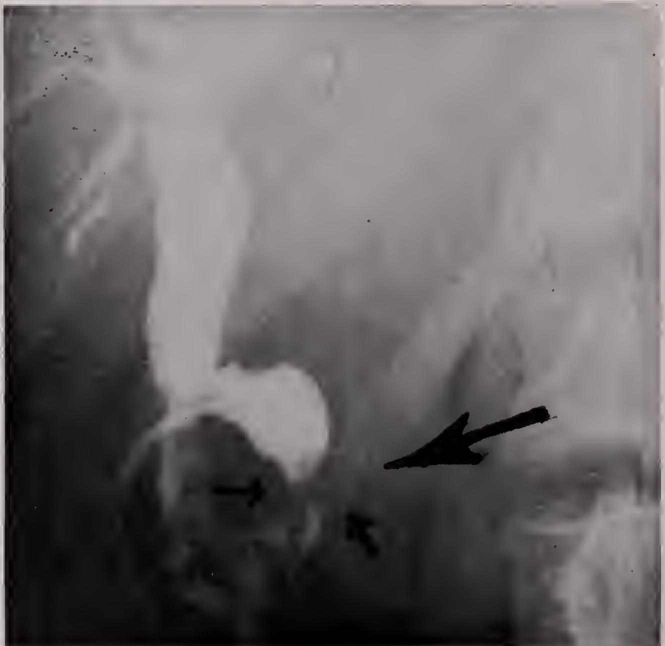

Fig. 1

of Vater into the duodenum. Stone forceps and scoops were passed down to the ampulla, but no grating or sensation of stone was noted. A number 6 dilator was then passed down the duct. This stopped at the point of maximal narrowing. Stick-ties were placed in the duct and the duct was opened at this point. It was then possible to identify a firm, round lesion measuring 10 millimeters in diameter attached to the medial wall. The lesion was excised with the terminal portion of the common duct and submitted for frozen section.

The pathologist reported that the common duct contained a poorly differentiated adenocarcinoma apparently arising from the glands of the common duct.

It was then decided to do a "Whipple procedure." Approximately one-third of the stomach was resected. The jejunum was sectioned distal to the ligament of Treitz. The common duct was transected proximal to the area where the T-tube had been placed. The pancreas was transected to the left of the portal vein.

Because the pancreatic duct was very small, the neck of the pancreas was inverted into the open end of the jejunum and sutured in place. The common bile duct was anastomosed to the jejunum two inches distal to the pancreatic anastomosis. The stomach was anastomosed to the side of the jejunum approximately eight inches from the choledochojejunostomy.

The patient tolerated the procedure well. When last seen on October 9, 1964, he was working full time, had maintained his weight at the postoperative level, and there were no evidences of recurrence.

Comments

"Classical signs" are not infallible. Repeated examination and attention to clinical findings are important. In this case perhaps the dilated biliary ductile system and gallbladder indicated the need for a better "cause" than "three small stone fragments." The diagnosis of carcinoma of the common bile duct prior to the onset of clinical jaundice is so uncommon that this diagnostic possibility is easily overlooked. The lack of growth of the lesion over a period of six months is striking. Some of the larger lesions involving most of the circumference of the duct must be present many months before jaundice occurs.

Neuro-Pediatrics Conference

Tuberous Sclerosis*

(Bourneville's Disease)**

This six-year-old white male was referred to the University of Minnesota Hospitals in November, 1963. He was the product of a normal pregnancy and a 48-hour labor. There was a prolonged second stage of delivery, and forceps were required. Examination of the newborn showed a cephalohematoma in the left occipitoparietal region and a mark on the face from the forceps. During the neonatal period he was fussy and irritable, had difficulty in handling his secretion, coughed and choked frequently. His developmental milestones were reached at the appropriate times. At 22 months of age he had a Coxsackie pharyngitis and a concurrent generalized convulsion characterized by stiffening and clonic movements of all extremities. A second generalized convulsion occurred later the same day. At age two he had a convulsion which lasted a little over an hour, associated with high fever, and at this time, he was hospitalized. An electroencephalogram was questionably abnormal, and he was discharged on phenobarbital. From age two to age 3½ he had short major convulsions every three months. In the spring of 1961 he began to have brief seizures characterized by lapse of consciousness and tightening of the muscles around the mouth. Dilantin® was added to the phenobarbital in an attempt to control these seizures, but he began to have more lapses, with his eyes rolling up and momentary cessation of all motor activity. He was then started on Tridione® and Mebaral.® In the fall of 1961, he was taking phenobarbital, Tridione,® and Dilantin.® His behavior became very difficult to manage and Thorazine® was added to his therapeutic regime. He continues to have generalized seizures once every three months, but had none in the year before coming to the University Hospitals. In the fall of 1963, his comportment became progressively worse, with agitated, hyperactive and erratic behavior. The past history and the review of symptoms are otherwise noncontributory. The family history shows no evidence of neurological disease. The patient's mother is a kindergarten teacher and appears very understanding of the entire situation.

---

*Held on Wednesday, November 18, 1964, at 3 p.m.

Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatric conferences are held the first and third Wednesdays of every month from 3:15 to 4:15 p.m. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Robert W. ten Bensel, in Pediatrics, and Dr. Robert Soll, in Adult Neurology.

**See Minnesota Med 47:271, 1964.

Continued

Dr. James DeVinck*

He appeared to be a well-developed, well-nourished, six-year-old male, who showed extreme hyperactivity during the entire examination. There is evidence of marked fluctuation in his attention span. His head circumference is 52 cm. Over the nose and cheeks there are very minute papular lesions measuring 1 to 2 mm. in diameter. There are several areas of vitiligo over the backs of the legs.

The remaining examination was normal except for mild bilateral incoordination of cerebellar nature. X rays of the skull were normal, showing no calcification. An electroencephalogram was reported as moderate to markedly abnormal with frequent multifocal isolated spike activity, mainly on the left. There was bilateral synchronous isolated spike and wave activity of high amplitude on the left, appearing to come from a deep focus. Because of the diagnosis of tuberous sclerosis, a consultation with dermatologists was obtained, their impression being that the skin lesions over the face were classic of adenoma sebaceum and that a biopsy was not necessary.

At this time, the child was started on phenobarbital, 60 mgm. three times a day and Desoxyn,® 5 mg. twice a day. After two weeks his hyperactivity diminished and his general behavior pattern improved. He still continues to have several seizures a day, but they appear less severe.

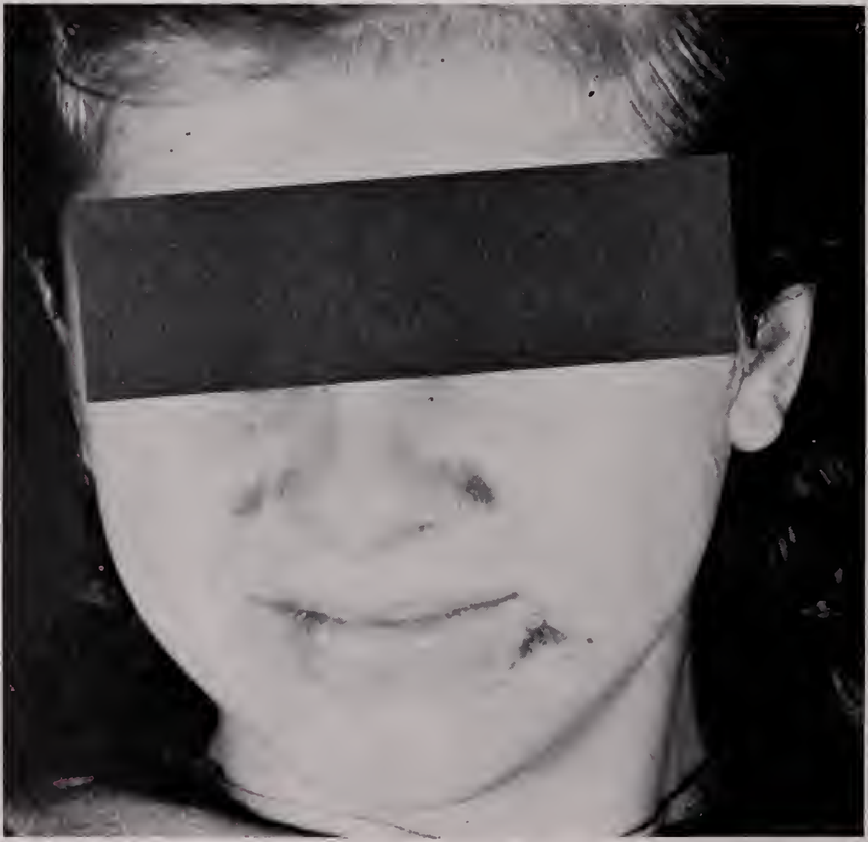

Fig. 1 — Adenoma sebaceum in a patient with tuberous sclerosis. Lesions may be very mild in young children but may be very prominent in the adult. (Fig. 2)

---

*Student physician, University of Minnesota Medical School.

Presently the phenobarbital dosage is 60 mg. in the morning, 60 mg. at 2 p.m., and 90 mg. at bedtime. He was tried on both Zarontin® and Celontin,® but again his behavior became worse, showing more irritability, destructiveness and inco-ordination.

In March of 1964 there was marked improvement in his behavior and he became more manageable; also his report card became more satisfactory. He was last seen October 28, 1964, at which time his seizures were essentially unchanged except that a few had been noted at school. The seizures occur in the morning with flexion of the head and chin. His behavior is generally good, but occasionally he had a poor day in school. At his last clinic visit he was begun on Librium,® 5 mg. twice a day.

Mrs. Ruth Agar*

At the present time he is reading a primer of 135 words and seems to have a good vocabulary with slight to good comprehension. Occasionally he blocks on words and in his ability to concentrate. He can write one to seven numbers, but it is felt that his understanding of the symbols is not clear. At times he needs to repeat his work and begins to stammer when he is excited. He appears to enjoy books and retells the stories which he hears. When working alone, he is easily distracted and, at times, "silly." He is in need of constant adult supervision in play and work.

Mrs. Hemstock**

He has petit-mal seizures every morning before attending school. His

Continued

mother does not usually dress him until after his seizures, as he urinates at this time. Two weeks ago, when his medications were changed, he suddenly became very accident-prone as a result of increased inco-ordination. The communication between the mother, school nurse, and school teachers is very good regarding his changes in medications. His school health record contains most of the pertinent information which is communicated from the mother to the school nurse.

Dr. Kenneth Swaiman*

Tuberous sclerosis is an uncommon neurological condition. This syndrome clinically consists of adenoma sebaceum, seizures, and difficulty with learning (mental deficiency). The course is progressive, as it appears to be in this patient. The findings which the patient manifests would assure one of the diagnosis of tuberous sclerosis with 95 to 98 per cent accuracy. The skin lesions are very striking when they are present, characterized by a nose blush of a papular, discrete character. They are caused by an increase of connective tissue and an increased capillary venular pattern, as well as associated increase in sebaceous glands. In the central nervous system the classical lesions are convolutional foci of sclerosis in which the gliosis is associated with gross disturbances of architecture.[1] These areas of gliosis may enlarge, forming "tubers" over the cortex, in the white matter and in the subependymal areas of the ventricles. In time these tubers may become malignant and grow very rapidly, similar to the glioblastoma multiforme of the adult. Brain tumors, however, are rare; among 29 patients Critchley and Earl[2] found only one example. The disease is not confined strictly to the central nervous system, as there may be an involvement of the heart, bones and kidneys. In the heart the disease is usually associated with rhabdomyomas, while the kidneys and bones may have hamartomas. The skin may also show discoloration over the area of the lumbar spine, called "shagreen" spots. Various developmental defects

---

*Pediatric neurologist, University of Minnesota Medical Center.

may also be found, such as congenital heart disease, harelip, spina bifida, and polydactylism.[3] The lungs are rarely affected.

The prognosis for this child is poor. Both his intellectual life and his social life are already compromised. Nothing is known that has been beneficial so far in halting the progressive nature of the disease and death often occurs early in the second decade.[3]

Dr. Edward Defoe, Jr.*

Tuberous sclerosis is usually considered a dominant disease with incomplete penetrance, although it may be sporadic in nature. This case probably represents a sporadic case, as there is no family history of the disease.

Dr. Harold Ireton**

In April 1964, the patient attained a score of 62 on the Stanford-Binet. His ability to identify pictured objects by name was less than adequate for an average four-year-old child. His ability to state the meaning of words was slightly better, but none the less below average for a child of his age. He should have yearly psychometric testing to determine whether there is any progression in his mental retardation. The parents might benefit from supportive counseling.

Mrs. Helen Moon†

The parents do need encouragement about the child's progress in school. In the Robbinsdale school system there are classes for those children with I.Q.'s of less than 80. The classes for the neurologically damaged are for those children with I.Q.'s above 80 and who have neurological handicaps. There are also eight rooms for slow learners.

Final Recommendations of the Conference

1. Dr. Roger Lienke‡ will work closely with the University staff in maintaining communication with the school as far as changes in medication and any further progressive neurological changes are concerned.
2. It is recommended that psychological testing be performed at fairly frequent intervals of one to two years to evaluate any further progressive mental retardation.
3. Those persons involved with the patient on a day-to-day basis should seek to give the parents emotional support in the handling of their child.

Infections of the Urinary Tract

Part V — Comments and Conclusions*

WILLIAM J. MARTIN, M.D.**
RICHARD D. WAGONER, M.D.**
Rochester, Minnesota

Toxic agents that may accumulate in the blood, such as streptomycin and even the bacteriostatic sulfonamides, nitrofurantoin, nalidixic acid, and methenamine mandelate, should be used with caution in patients who have borderline renal insufficiency. If renal function is less than normal, the doses of such drugs should be correspondingly reduced or eliminated.

There are four antibiotics capable of ototoxicity: streptomycin, neomycin, kanamycin, and vancomycin; by allowing these agents to accumulate in the blood, renal insufficiency may increase their ill effects on the eighth cranial nerve. Detection of early vestibular and cochlear complications can best be effected when audiometric and vestibular turning tests are done before therapy with a potentially ototoxic antibiotic is begun, periodically during treatment, and again six months after its cessation. Concurrent use of ototoxic drugs should be avoided and caution should be exercised in patients to whom such drugs have been administered previously. Older patients especially should be carefully observed for signs of damage to the eighth cranial nerve.

Agents described as having a potentially direct nephrotoxic effect are the sulfonamides, streptomycin, neomycin, kanamycin, bacitracin, vancomycin, polymyxin B, colistin, amphotericin B, and outmoded or degraded tetracyclines. Whether methicillin and cephalothin have such an effect is uncertain.

Penicillin, erythromycin, and chloramphenicol are three antibiotics of which the renal route of excretion is largely tubular; consequently in azotemic patients receiving these drugs, there is less concern regarding abnormally high blood levels and their duration than with drugs having a glomerular route of excretion.

Antibiotics capable of producing neuromuscular block similar to that induced by d-tubocurarine chloride include streptomycin, dihydrostreptomycin, neomycin, kanamycin, and polymyxin B. Colistin may have a similar effect. Curare-like effects have been noted after instillation of these drugs intrapleurally as well as intraperitoneally. Similar effects have followed intravenous administration of kanamycin, which might alert one to the possibility of their appearance when polymyxin B is given by that route. Anoxia, sometimes associated with anesthesia, may enhance the antibiotic-induced curare-like effects. Failure to reverse the untoward reaction may eventuate in respiratory and cardiac arrest. Neostigmine and calcium gluconate have been suggested in management of the reaction. The physician should bear in mind the theoretic possibility of this effect in patients receiving neomycin-polymyxin B rinse via indwelling urethral catheter.

Administration of a sulfonamide in full dosage to a woman near term requires caution because of the possibility of producing hyperbilirubinemia by releasing protein-bound blood bilirubin with consequent kernicterus in the fetus. Probably all sulfonamides are contraindicated for premature and newborn infants for the first weeks of life because of their undeveloped enzyme systems and immature hepatic and renal function.

Nephrotoxicity due to the sulfonamides may occur via two mechanisms: (1) precipitation of the drug, especially the acetylated derivative, in the tubules, and (2) hypersensitivity. Crystallization in the renal tubules is encouraged by a less than adequate

Continued

**Section of Medicine, Mayo Clinic and Mayo Foundation.

daily output of urine. Because the solubility of both free and acetylated sulfonamide is greater in a neutral or alkaline medium, alkalinization of the urine has been attempted in an effort to decrease crystallization. However, alkalinization increases the rate of excretion of the sulfonamide, lowers the concentration in the blood, and requires increased administration to produce tissue bacteriostasis. Sulfisoxazole (Gantrasin) and sulfisomidine (Elkosin) are more soluble in urine of variable pH than are sulfadiazine and sulfamerazine. Special care may be required with sulfamethoxazole (Gantinol) to avoid crystalluria because of the high degree of acetylation of the drug in the urine.

In certain infections in which response is incomplete and in which microbiologic studies demonstrate that the pathogen remains sensitive to an antibacterial regimen, continuation of the same regimen, perhaps with increased dosage, may control the process. In other words, failure of response may reflect either the duration or the total dosage of the regimen employed and does not necessarily require resort to a different drug.

Adjustment of urinary pH has been said to enhance the activity of drugs in the management of urinary infections.[21] Antibacterial activity of streptomycin, neomycin, kanamycin, penicillin, and erythromycin against organisms causing urinary infections may be augmented at alkaline pH, whereas the tetracyclines, cycloserine, and novobiocin may be more potent at acid pH. It is said that results with sulfonamides and chloramphenicol vary with the organisms tested, and that the action of nitrofurantoin is not influenced by pH adjustments. A 20 per cent increase in effectiveness has been claimed for the procedure.[21]

Cycloserine (Seromycin) may have a place as a second-line agent in the management of selected infections of the urinary tract when conventional agents have failed and before drugs with greater toxic potential are employed. In addition to its tuberculostatic effect, cycloserine is active against coli-aerogenes and enterococcal and staphylococcal organisms; Pseudomonas and Proteus organisms often are resistant to the action of the drug. In-vitro susceptibility testing should be carried out with a synthetic alanine-free culture medium because of the phenomenon of alanine-cycloserine antagonism. In adults with normal renal function, the maximal oral dosage is 250 mg. of the agent every six to 12 hours, and blood concentrations of cycloserine in the range of 25 to 30 μg. per milliliter should not be exceeded. Side effects are most likely to occur after administration of more than 1 gm. of cycloserine daily, particularly when the individual dose exceeds 250 mg. Reportedly, untoward effects of cycloserine on the nervous system, such as mental confusion, hypomania, dyskinesia, and convulsions, are controlled by administration of pyridoxine alone or in combination with anticonvulsants. The drug should be used cautiously in face of renal dysfunction and is contraindicated in epileptics.[20]

Combinations of antibacterial agents should be reserved for situations demanding coverage while microbiologic data are awaited, for polymicrobic infections, and for instances of infections in which there are indications that an enhanced effect is possible. The use of multiple agents not only is unnecessary in most cases of urinary infection but might increase bacterial resistance more than if patients were treated with a minimal number of antibacterial drugs. Indiscriminate use of multiple agents may increase bacterial resistance, since such resistance appears to be a direct function of the total amount of a given antibacterial drug used in a given community.

It should be constantly recalled that antibacterial agents are not an unmixed blessing, because their use may result in a diagnostic loss if they are employed before diagnosis is established; they may cause emergence of resistant organisms; they may produce untoward reactions, and they are expensive.

Patients with acute pyelonephritis frequently are rather ill and should be at complete rest in bed. They may require hospitalization and intravenous fluids to combat dehydration. If there is no contraindication, fluids should be forced until the daily intake exceeds 3000 ml. Acute infections of the urinary tract should be treated for at least one week after all symptoms have subsided and after the results of cultures are negative; chronic infections warrant even longer treatment after arrest of the process. It is important that prior to cessation of therapy, additional urinalyses and cultures be obtained, and these should be repeated one to three months after treatment is stopped, or sooner if symptoms warrant. The optimal duration of treatment in an individual urinary infection actually is not known, and it may be that conclusions in this regard cannot be generic. However, it appears that as one's experience with antibacterial agents has increased in the management of urinary infections, the recommended duration of treatment has correspondingly lengthened. Treatment of acute infection of the urinary tract usually is much more successful than is treatment of chronic infection. In most cases, vigorous therapy with a pertinent drug controls acute infection if obstruction is not present. However, chronic infection is often compatible with many years of life. Even when decompensation appears, it may progress so slowly that the individual maintains his usual activity for months or years despite considerable azotemia. "Cure" can be determined only by the patient's response from both the clinical and the laboratory point of view after cessation of therapy.

In patients with persistent or recurrent infection that prompts more complete investigation, a minimal study should include determination of the blood urea, repetition of urinalysis and urine culture with in-vitro susceptibility studies, intravenous pyelography, cystoscopy, and, if possible, a cinefluoroscopic study.

In addition to the relieving of any obstruction to the passage of urine before antibacterial agents can become effective, surgical procedures such as drainage of an abscess or nephrectomy occasionally are necessary. Adequate removal of demonstrated obstruction may bring about cure of an infection, but more often eradication of pathogens in such cases requires conjoint antimicrobial therapy. Pyelonephritis is at least 10 times more frequently found in an obstructed urinary tract than in a normal one.

Infection may persist in spite of therapy, especially when bacteriostatic agents have been used. Scrutiny should not be relaxed because urine cultures become negative, especially after the use of bacteriostatic agents; later events may indicate that the infection was not completely controlled but continued to smoulder despite the negative cultural results, and it becomes acutely manifest after a short time. This is why, in more than simple acute infections, an antibacterial regimen with a bactericidal effect often is preferred, considering comparative toxicity and routes of administration. Eradication of bacteriuria during or shortly after the cessation of therapy indicates only achievement of an adequate antibacterial effect in the urine but does not assess the value of the regimen in deep-seated infections. Some of these infections "burn out"; some may continue indefinitely without appreciable deterioration of renal function, and some may culminate in renal insufficiency.

Failure in the management of an infection of the urinary tract should prompt consideration of the nature of the lesion, since underlying disease may make recovery impossible.

Conclusions

The principles of management in infections of the urinary tract can be summarized as follows: (1) identify bacteria by the gram stain and procure cultures and bacterial susceptibility tests in more severe, recurrent or chronic infections; (2) when bacteria are identified, initiate treatment with antibacterial agents on an empirical basis if the condition of the patient warrants; (3) search out and attempt to correct any condition that predisposes to infection; (4) initiate procedures to assure free access of the antibacterial agents to the site of the infection, and (5) ensure adequate drainage of the urine when indicated. Since acute, simple infections of the urinary tract are common, use of nonantibiotic antibacterial agents such as the sulfonamides in the

Continued

therapy of urinary infections has a continued place in the therapeutic armamentarium; however, diagnosis should be as exact as possible so that treatment of more serious infections with less than adequate agents is avoided. If agents such as the sulfonamides fail to eradicate an infection that appeared to be an acute simple one, then further urologic and microbiologic investigation should be carried out.

An outline of the antibacterial regimens currently applicable to urinary infections might be the following:

1. Preliminary empiric therapy, often in the form of nonantibiotic agents, is given patients with acute infection but without overt evidences of underlying uropathy or predisposing disease. 2. Definitive therapy is given patients with infections that remain after attempted correction of uropathy, patients with marked systemic reaction especially if prior therapy has been unsuccessful, or patients in whom a last desperate effort is being made to preserve renal function. (In these and similar patients, antibiotics are generally used and then in accordance with careful microbiologic and urologic investigation.) 3. Intermittent prophylactic therapy is one in which chemotherapy is given the first five to seven days monthly for several months to patients with acute recurrent infection after negative investigation for underlying uropathy or predisposing disease. 4. Suppressive therapy is given patients with chronic infection not susceptible to eradication but in whom attempts to minimize renal damage and symptoms are made. Often nonantibiotic agents, except possibly nitrofurantoin, are used and may be given continuously or intermittently, or drugs may be alternated in an attempt to avoid unilateral dislocation of the body flora and induction of bacterial resistance. Use of nitrofurantoin is avoided in some of these patients since long-term therapy in patients with decreased renal function may be complicated by polyneuropathy. Although permanent sterilization of the urine in chronic, complicated infection may be achievable in no more than 20 per cent of cases, infection can be eliminated temporarily in about 70 per cent. With this latter rate of achievability in mind, suppressive therapy is desirable in an attempt to minimize renal destruction.

Asymptomatic bacteriuria may be demonstrated prior to the onset of clinical manifestation in acute and recurrent infections. Under such circumstances the nonantibiotic antibacterial agents are often used just as they are employed in more overt infections. As an example of such management, administration of a sulfonamide to a pregnant woman may eliminate the bacteriuria and prevent acute pyelonephritis. When asymptomatic bacteriuria manifests chronic infection and when obstructive uropathy and predisposing disease are eliminated, definitive therapy may be attempted. If such treatment is not pertinent or has been unsuccessful, suppressive therapy can be given. Asymptomatic bacteriuria is most often detected because of close scrutiny given to likely victims.

Careful analysis of the individual infection and the use of common sense in therapy are urged; there is no place for diagnostic or therapeutic dogma in urinary infections. Not all urinary infections can be eradicated any more than can all disease in any sphere of medical endeavor, but failure to control a given urinary infection promptly should not generate pessimism sufficient to cause abandonment of all therapeutic effort. It may be necessary at any stage in the management of infections of the urinary tract to re-evaluate, re-examine, and alter any regimen. Adequate management of infections of the urinary tract requires close cooperation between the internist and the urologist in selected cases. Careful follow-up of every patient having had infection of the urinary tract is mandatory.

Grand Rounds

Polycystic Kidney Disease*

In spite of the extensive medical literature that has accumulated about polycystic kidney disease, its etiology and treatment are still not well understood, and the disease has a poor prognosis.

Etiology

In the course of the last century, a number of theories were proposed but none accepted universally.

Virchow in 1856 reported that the cysts were formed secondary to obstruction of the urinary flow, caused by uric-acid crystals or atresia of papillary ducts secondary to pyelonephritis or papillitis.[1]

In 1856 Kupffer showed that the kidney was formed from two different sources: the mesonephric duct and the metanephrogenic anlage. Hildebrand in 1894 postulated that the etiology of polycystic kidney was due to the failure of these two parts to unite.[2] Albrecht, Herxheimer and Nicholson proposed that the etiology was neoplastic.[2] Kampmeir in 1923, and also with McKenna in 1933, proposed that there was persistence of the first, second and third generation "nephron." Those "nephrons" usually disappear, but in polycystic kidney disease they may persist and subsequently lead to cyst formation.[2]

Heplers in 1930 suggested that reduction in the renal blood flow leads to cystic degeneration of the kidney.[3] Roos in 1941 attributed the etiology to defective germ plasm.[2] Lambert in 1947 showed with serial kidney sections that many adult cysts communicate with tubules, while in the neonatal polycystic kidney the cysts are closed.[4]

Bricker and Patton in 1955 demonstrated with inulin and P-aminohippurate injection that many of the cysts in adults, but only a few of those in children, were in functional connection with open nephrons. These facts, together with the finding of hereditary polycystic kidney in goldfish which

Continued

---

*Medical Grand Rounds, Mt. Sinai Hospital, December 22, 1964.

have a mesonephric kidney, tend to rule out the earlier theories of Hildebrand and Kampmeir.[5]

Allen postulated that the normal development of the ureteric bud has an "organizer" effect on the metanephrogenic mass which permits canalization of tubules. Defective action of this "organizer" may result in atresia of tubules and subsequent cyst formation.[6]

Recently Potter and Osathanondh, by applying microdissection technique on kidneys from 70 normal foetuses, infants, and adults, demonstrated that the collecting tubules develop from repeated branching of the ureteral bud. The first branches of ureteral bud consist of the ampullary portion, which is the area of growth at the end of the tubule, and the interstitial portion. The ampullae normally induce formation of nephrons, then disappear; while the interstitial portion of the tubule persists.[2] In comparison, they did microdissection on cystic kidneys obtained from 30 patients with polycystic kidney disease, ranging in age from newborn to 67 years and found that the main abnormality was in the collecting tubules. They described four pathogenetic types of polycystic kidney:

Type 1: Bilateral symmetrical enlargement of the kidneys where the surfaces are essentially smooth, although they contain small cysts, 1-2 mm. in diameter, due to hyperplasia of the interstitial portions of the collecting tubules. This condition is always accompanied by intrahepatic cystic proliferation of bile ducts and, to a lesser extent, by cysts in the lungs or pancreas, and is invariably fatal in early life. This is the only variety found in siblings and may be caused by a homozygous state of recessive genes.

Type 2: Either bilateral, unilateral or only part of one kidney affected. When both kidneys are involved, the condition is always fatal after birth. When unilateral or when only part of the kidney is involved, the condition may be found in childhood or adulthood; or it may be symptomless. This variety is associated with malformation of other organs but not accompanied by hyperplasia of bile ducts. The main abnormality in this type is inhibition of ampullary activity, resulting in cessation of nephron formation, prevention of the tubules from further branching, and subsequent cyst formation.

Type 3: Always present at birth and usually bilateral, with the kidneys larger than normal. Frequently a family history of polycystic kidney is found. The abnormalities are in both the ampullary and interstitial portion of the collecting tubules. The most common sites of cyst formation are the angle of Henle's loop, Bowman's capsule, and the proximal convoluted tubules; all the cysts are connected to the tubules which communicate with the renal pelvis. The age at which the symptoms become manifest varies according to the proportion of normal to abnormal tissue. In general, this group includes all bilateral cystic kidneys found in individuals more than a few weeks of age. This type is generally designated as polycystic kidney of adults.

Type 4: Caused by urethral or ureteral obstruction in early foetal life, resulting in back pressure which subsequently affects the tubular development, resulting in cyst formation. The severity of the disease depends on the degree and the time of onset of obstruction.

Incidence

Bell in 1950 examined combined statistics of autopsy material collected from the literature and found an incidence of 1:351.[1] He also found that in 240 stillbirths the incidence increased to 1:200. Campbell studied 19,046 autopsies in children and found 72 cases, i.e., an incidence of 1:265, with a slightly higher incidence in males.[3]

Book in 1951 found in a Swedish group an incidence of 0.7 per 10,000 births.[1] Simon and Thompson studied 366 cases of polycystic kidney seen at the Mayo Clinic in the period between 1925 and 1944 and found a clinical incidence of 1:2438 and an autopsy incidence of 1:323. In the same series, 80% of the patients were in the fourth to sixth decade. The average age was 44 years; 55.5% were males and 44.5% females.[7] Most authorities agree that there is no sex predilection, and in many instances the disease is transmitted by a recessive autosomal gene which appears at two age peaks, in infancy and in adulthood, and is frequently associated with other anomalies.

Pathology

Gross

Rall and Odell in their review of the literature found that the disease affects one kidney in 4 to 13% of cases.[8] Campbell considers the incidence of unilateral polycystic kidney not to be reliable since the opposite kidney, which appears grossly normal, may be involved microscopically.[3] Macroscopically the kidneys are usually enlarged and the surface is irregular and knobby due to the presence of cysts which vary in size from microscopic to several centimeters in diameter. In infants the cysts are mainly small, so that the surface may be finely pored.[1]

The cut surface has a honeycomb appearance. The cysts contain fluid which may be thin watery, yellowish or dark brown due to hemorrhage or frank pus from secondary infection.[1] According to Campbell, the cystic fluid has a specific gravity of 1.004-1.006 and may contain cholesterol, leucine, cystine, uric acid, calcium, oxalate, red blood cells, or pus cells.[3]

Microscopic

The cysts are distributed in cortex and medulla. They are lined by cuboidal epithelium which is usually flattened, and there is infiltration of macrophages, red blood cells, and white cells.

Associated Diseases

According to Simon and Thompson there is associated nephrolithiasis in 14.1% of the cases, probably due to urinary stagnation and infection leading to stone formation.[7] Polycystic kidney has rarely been associated with malignant tumors,[1] but hypernephroma and Wilm's tumor have been described with the disease.[1,9,10]

Polycystic kidney may be associated with anomalous formation of other organs. In 5% of the cases there is association with cystic liver and in 4% association with splenic cysts[3]. Sixteen and six-tenths per cent of patients with polycystic kidney have intracranial aneurysm and 4% of patients with intracranial aneurysms have polycystic kidney.[11,12] A syndrome of

Continued

bilateral polycystic kidney, polycystic liver, and congenital aneurysm of the basal arteries of the brain has been described by Gates.[1] Cysts have been found in ovaries, uterus, esophagus, cerebrum, cerebellum, pancreas, thyroid, bladder, testes, and epididymis.[1] Association of the disease with aneurysm of the splenic and renal arteries has been described.[13]

McCaughey et al. reviewed Mayo Clinic records from 1946 through 1961 and reported 19 cases of neonatal polycystic kidney disease with brain defect.[14] Dalgaard in his classical review noted seven cases of polycystic kidney associated with brain defect out of 40 neonatal cases.[1] Shands reported simultaneous polycystic kidney and erythroblastosis foetalis in three successive siblings.[15] Campbell in his autopsy series of 72 cases of the disease in infants and children found association of patent foramen ovale in 10, patent ductus arteriosus in five and interventricular septal defect and dextroaortic position in one each.[3]

Pathological Physiology

Lambert subjected two moribund patients with polycystic kidney to intraperitoneal injections of inulin and then demonstrated the presence of inulin in samples of cystic fluid taken immediately after death. He concluded that cystic nephrons in adults retain their function and take part in the formation of urine.[4] This study has been confirmed by Bricker and Patton who performed in vivo experiments in polycystic kidney and on kidneys with simple cysts, by intravenous injections of inulin, P-aminohippurate and creatinine, and found that many of the cysts in five adults and some of the cysts in children were functionally in connection with open nephrons.[5]

Clinical Manifestations

Infancy and Childhood

The disease manifests itself in relation to the degree of renal involvement. It may involve both kidneys completely and cause stillbirth. The kidneys may be very large and cause prolongation of labor and uterine rupture, with respiratory and circulatory difficulties in the infant, endangering his life.

Children manifest striking features: protuberant abdomen and renal facies, described by Potter as consisting of large low set ears, marked inner canthal folds, broad flat nose, microganthia, and often broad, clumsy spade-like hands.[16] Cyanosis and shallow breathing are noted, and respiratory difficulties dominate. Uremia, pain, pyuria, haematuria, and hypertension are noted in children surviving the neonatal period.[14] Fergusson found that the parents of the affected infants appeared normal on clinical and pyelographic examination, an observation implying that the adult form of polycystic kidney is an etiologically different disorder.[17]

In Adults

In the table following are listed the main signs and symptoms of polycystic kidney disease in a series of 366 patients from the Mayo Clinic compared to Dalgaard's series of 350 patients from Denmark.[1,7]

Recently the association of polycythemia with polycystic kidney disease has been described.[18-22] This may be due to increase in erythropoietin activity. It has been reported that erythropoietin is present in greater concentration in the cyst wall than in the cyst fluid, so it is doubtful that cure of polycythemia can be obtained by puncture or aspiration of cysts.[19]

Dalgaard reported four cases of cystic ovaries in 350 patients with polycystic kidney disease.[1] Campbell reported one case of cystic ovaries in his series.[3] A case has been reported from the Massachusetts General Hospital of a 65-year-old female who had polycystic kidney, polycystic liver, pancreatic cysts, and papillary cystadenocarcinoma of one ovary. The other ovary had been removed because of "ovarian cyst" 20 years prior to her death.[28]

TABLE I

Signs & Symptoms	% of Patients (Mayo Clinic) (7)	% of Patients (Dalgaard's Series, Denmark) (1)
Pain	44.5%	59 %
Haematuria	50 %	45 %
Urinary infection: fever, frequency, etc.	33.3%	—
Gastrointestinal symptoms	7.7%	—
Cardiovascular symptoms including hypertension	—	46 %
Bilateral palpable kidneys	51.1%	38.8%
Unilateral palpable kidney	26.8%	22 %
Hypertension	56.1%	28 %
Proteinurea	Majority	74.6%
Pyurea	43.2%	45.7%
Renal insufficiency	47 %	31.5%
Anemia	28.7%	—
Urographic studies	78.8%	—

Urography

Excretory or retrograde urography shows elongation, irregular enlargement, and crescentic deformities (Wine-Glass sign) of calyces. Dalgaard pointed out that the urograms show only the gross anatomical changes, which need not parallel the renal functional impairment.[1]

Prognosis

The infantile type of the disease is rapidly fatal, due to uremia or complications. In the adult type, Dalgaard pointed out that the average age at death was 51.5 years, identical for males and females, and varying between 25 and 85 years. Forty-five per cent (45%) died before the 50th year and 22% after the 60th year.[1] The five-year survival in Simon's series was 56%, while the 10-year survival was 38%.

Causes of Death

In the Dalgaard series 59% died of uremia, 13% from cerebral hemorrhage, 6% from heart disease, and 22% from other causes.[1] Of 193 women with polycystic kidney, 65% were pregnant once or several times; 61% had one or more live births; and only one died during pregnancy.[1]

Treatment

An effective treatment is not available. Whether this disease should be handled conservatively, with surgery utilized only for specific urological

Continued

complications, or whether there is a place for prophylactic surgical decompression to preserve functioning renal tissue is not now known. The urologic complications for which surgery may be required are: nephrolithiasis, infection, associated neoplasm, tuberculosis, hematuria, or intractable pain.[7] In reviewing the literature on decompression of cysts, Dalgaard points out the lack of evidence of improvement, although many felt that decompression improved renal function and the prognosis.[1]

Goldstein in 1951 attempted to compare, in terms of survival, the results in patients having decompression versus those not undergoing surgery.[23] He revised his series in 1960, totalling 57 patients, and reported that those having decompression lived an average 4.9 years longer, compared to 2.3 years for patients not treated surgically.[24] Patton and Bricker in 1954 reported two cases in which they found deterioration in renal function after decompression by surgery.[25]

Seven cases of polycystic kidney, in which unilateral surgical decompression had been carried out and evaluated pre and postoperatively by differential glomerular filtration studies, allowing the nontreated kidney to serve as a control, showed deterioration in function of the treated kidney postoperatively.[26] The best hope in treating this disease appears to be renal transplantation.[27]

Case Summary

This was the second hospital admission for this 28-year-old white female who was admitted 11/19/64 and discharged 11/24/64. Her chief complaint was pain in the right flank beginning the morning of admission.

Family History

The mother has polycystic kidney disease. The maternal grandmother died of the disease.

Past History

The patient had had a similar episode of pain eight years previously. On 2/15/63 she was admitted to Mount Sinai Hospital because of severe colicky pain in the left flank accompanied by nausea, vomiting and chills. The findings at that time were blood pressure 200/140 and hirsutism of the face and thighs. Cystoscopy showed a small calculus at the left ureteral orifice. Admission IVP revealed bilateral polycystic kidneys with a nonfunctioning left kidney. The fundi showed A-V nicking. Urinalysis revealed microscopic hematuria and pyuria, and urine culture grew E.coli. 17-ketosteroids were 13.7 mg. in 24 hrs. Sex chromatin pattern was positive. After being treated with terramycin and analgesics she became asymptomatic. The discharge IVP showed prompt dye excretion bilaterally with disappearance of the obstruction at the left ureteral orifice. She was followed in the Outpatient Department and had several urinary tract infections treated with antibiotics. On one occasion she had gross hematuria.

Gynecological History

She had menstruated three to four times in the past since the age of 13 years. Her last menstrual period was eight years ago. She had been married twice and had had no pregnancies.

Present Admission

Blood pressure was 190/130. There was hair on the face and thighs with a male configuration of pubic hair. BUN 23 mg%, uric acid 7 mg%, white blood count 10,000 cells. Urinalysis: albuminuria 1+, rbc 70-80 and wbc 20-25 per hpf. Urine culture: more than 100,000 colonies of E.coli/cc. Temperature varied between 99.4 and 101. She was treated with analgesics and tetracycline with improvement. Subsequent urine cultures were negative.

She was discharged on the sixth hospital day to be followed in the Outpatient Department. Discharge diagnoses were: (1) polycystic kidney disease, bilateral, adult type, with hypertension and renal insufficiency; (2) chronic pyelonephritis; and (3) Stein-Leventhal syndrome (clinical diagnosis).

For Gout and Gravel

Thomas Sydenham (1624-1689) English internist, known as the English Hippocrates, describes his self treatment for gout and gravel as follows:

"In the morning, when I rise, I drink a dish or two of tea, and then ride in my coach till noon; when I return home, I moderately refresh myself with any sort of meat, of easy digestion, that I like (for moderation is necessary above all things), I drink somewhat more than a quarter of a pint of canary wine, immediately after dinner, every day, to promote digestion of the food in my stomach, and to drive the gout from my bowels. When I have dined, I betake myself to my coach again and when business will permit, I ride into the country two or three miles for good air. A draught of small beer is to me instead of supper, and I take another draught when I am in bed, and about to compose myself to sleep."*

Remedies for the Itch*

The itch in man is cured very effectually by using the marrow of an ass, or the urine of that animal, applied with the mud it has formed upon the ground. Butter, too, is very good; as also in the case of beasts of burden, if applied with warmed resin: bull glue is also used, melted in vinegar, and incorporated with lime; or goat's gall, mixed with calcined alum.

Star-spangled money saver

Used properly, this red, white and blue writing "tool" can take care of your money-saving problems in a single stroke.

You just grasp it firmly and put your John Hancock on an application for the Payroll Savings Plan where you work.

This authorizes your employer to make your savings automatic. He sets aside a small amount from your check each payday toward the purchase of U. S. Savings Bonds.

The amount can be any size. The important thing is it's saved regularly.

Don't worry if you have to use an ordinary pen instead of a star-spangled one. You'll get a nice star-spangled feeling to make up for it.

Quicks facts about
Series E Savings Bonds

- ✓ You get back $4 for every $3 at maturity
- ✓ You can get your money when you need it
- ✓ You pay no state or local income tax on the interest and can defer federal tax until you cash the Bond.
- ✓ Your Bonds are replaced free if lost, destroyed or stolen

Abstracts, Briefs and Commentaries

SEPTIC ABORTION

The article reviews 677 cases of abortion treated between 1957 and 1962 with special emphasis on 95 (14%) cases with sepsis. The typical patient was in her late twenties, had had at least one previous pregnancy, and was in the 11th week of gestation. Two thirds were married. One fourth admitted some attempt to induce abortion.

Seventy-two patients were never dangerously ill and all but two left the hospital within five and one-half days. These two remained longer because of hypofibrinogenemia in one and collagen disease in the other.

Twenty-three patients were classified as seriously ill. These patients had an appropriate history and cardiovascular collapse, whether they were febrile or not. Also severely ill but less obviously so were those with an appropriate history who continued to be febrile and did not improve or got worse despite adequate antibiotics and fluid replacement. Of these ill patients 12 complained of chills and fever, whereas only one fifth of the less ill reported these symptoms. The authors suggest that only the presence of shaking chills and fever was helpful as a prognostic sign. Leucocytosis was not of prognostic value in either the seriously ill or in those less ill.

Patients who were afebrile on admission were treated with antibiotics and early curettage. Although the efficacy of their use was questioned, antibiotics, if used preoperatively, should be given to establish adequate blood levels before uterine manipulation.

Chemically-induced abortion followed by massive collapse precludes surgery. Autopsies among this kind of patient show adrenal hemorrhage and necrosis, acute renal tubular necrosis and pulmonary edema. Dialysis and measures to combat anemia may be life-saving.

Clostridial infection is suspected in the presence of continued abdominal pain associated with muscle aches, crepitus, chills, fever, nausea and vomiting. Surgery must be considered if the patient does not improve after 12 hours of medical management with antitoxins, massive doses of antibiotics, colloid and electrolyte replacement. Curettage may suffice; but if hypotension occurs during the procedure, immediate hysterectomy is recommended. Hyperbaric oxygen and dialysis may be used.

Early hysterectomy (within 12 hours) is recommended when gram-

Continued

negative organisms are present on the cervical smear and hypotension is present.

APPENDICITIS IN INFANTS

The first comprehensive description of appendicitis was by R. H. Fitz in the *American Journal of Medical Science* in 1886. The extremes of life are largely responsible for the mortality from this disease. Cases in the first two years of life make up about 2 percent of the total cases in children and about 0.2 percent of all cases.

In the past ten years, 17 cases in children under two years old were seen in the Los Angeles Children's Hospital; three of these children were under a year old. The average duration of symptoms on admission was 3.8 days. About a third of the patients had diarrhea.

Fourteen children were operated on after intervals ranging from two hours to five days. All but one had a primary appendectomy; the exception was a simple drainage with a secondary appendectomy. The average stay in hospital was 13 days. The over-all mortality was 12 percent.

A mortality of around 10 to 15 percent for children under two years old seems to be the irreducible minimum until the disease can be recognized earlier. The difficulty of early recognition is illustrated by the fact that 88 percent of the youngest children were found at operation to have a perforated appendix.

Abdominal pain, vomiting and fever are nearly always present in children with appendicitis. Before vomiting and fever start, pathologic involvement of the alimentary tract is suggested by behavior changes, irritability and restlessness as symptoms of pain, and sleeplessness.

Irritability associated with meals is particularly significant, for it is suggestive of painful intestinal peristalsis. Diminished peristalsis accompanied by abdominal distention is an indication of impending perforation. Relief of pain by flexing the hips is a significant sign. A pulse rate of over 180 per minute is a reflection of developing toxicity.

Pain and tenderness are rarely localized in infants. The palpation of a mass on rectal examination is significant. The diagnosis may be made more difficult by the frequent co-existence of respiratory or intestinal infections, or by the masking of symptoms by the administration of antibiotics.

In toxic infants great value is attached to active preoperative preparation, with intravenous fluids, electrolytes, plasma and blood, oxygen, nasogastric suction and antibiotics. No rigid criteria can be laid down for the operation time.

There were two deaths in the 17 cases, but none in the cases treated by operation.

CERVICAL ESOPHAGOSCOPY

Technic and Use

The use of cervical esophagostomy is an uncommon procedure. The authors state that it has three advantages over gastrostomy: 1, The transperitoneal approach is avoided; 2, The operation is more simple and should take less time; 3, The reflux of a feeding formula is no problem.

Klopp has used this approach in carcinoma of the esophagus, but it cannot be employed if obstruction forbids the passage of a tube. Ketcham uses the method routinely, when indicated, and has performed 168 esophagostomies. However, most surgeons unacquainted with the procedure and its indications prefer gastrostomy. The authors feel that esophagostomy is the choice when tube feeding must be employed over a long period of time (more than one week), as nasopharyngeal discomfort may be severe and cricoiditis may occur. Other indications for the procedure include major surgery for carcinoma involving the tongue, mouth, jaws, etc., and for the acute response to interstitial or external irradiation of the same areas.

The Cleveland Clinic has performed esophagostomy nine times: thrice for carcinoma of the tongue, twice for recurrent squamous carcinoma of the buccal mucosa, twice for malignant melanoma of the maxillary mucoperisteum, and once each for squamous cell carcinoma of the floor of the mouth, and for fibrosarcoma of the maxilla. Two of these patients have been successfully fed by esophagostomy over considerable periods of time, and a third patient will probably continue tube feeding as long as he lives.

Changing the esophagostomy tube is very simply done after one week. When the tube is no longer needed, it may be removed, after which the fistula closes spontaneously in a very short time.

Technic

Local anesthesia lends itself well to this procedure, but intravenous anesthesia may be preferred. A nasogastric catheter is introduced preoperatively. A short incision is made two fingerbreadths above and parallel to the upper border of the clavicle, exposing the anterior border of the sternomastoid muscle. The authors stress the importance of placing the incision as indicated, as the area for the incision in the esophagus is retrotracheal. The tissues are spread and the contents of the carotid sheath are retracted laterally. The finger advances in a posteromedial direction to the body of the seventh cervical vertebra. The thyrolaryngeal structures and trachea lie anteromedial. The index finger feels the previously passed nasogastric tube, and the esophagus is mobilized behind the trachea. With the tube still as a guide, the esophagus is fixed between two sutures. A puncture incision is made between these two sutures and a #16 French Levin tube introduced and advanced to the stomach. The nasogastric tube is removed. The esophageal incision is closed around the French catheter, and the skin incision is brought together around the tube loosely to permit free drainage. The tube is firmly anchored to the adjacent skin.

During the blunt dissection the recurrent laryngeal nerve and the inferior thyroid artery may be exposed.

The above procedure, as described by the authors, appears very simple. Infection with invasion of the mediastinum, usually considered hazardous,

Continued

has been of little or no concern. I have personally observed fatal aspiration pneumonia from regurgitation about a nasogastric tube.

We have never used esophagostomy for feeding, but the seeming simplicity of the procedure and its successful use by others would certainly favor its consideration when indicated.

TESTICULAR TORSION

Angell reports 16 recent cases of torsion of the testicle. Disturbingly few cases are diagnosed in time to save the organ. Many are wrongly treated, masquerading as epididymitis, and proceed unchecked to testicular atrophy. Two mistaken beliefs are responsible: that torsion is uncommon and that it seldom resembles inflammation.

An appreciation of the anatomical anomaly in torsion of the fully descended testicle is essential for correct diagnosis and treatment. The two layers of the tunica vaginalis, which normally invest the testis alone, extend upward to cover the whole epididymis and the cord, sometimes as high as the inguinal canal.

In addition, the testis is often separated from the epididymis by a lengthened mesorchium, longest at the upper pole, which enables the testis to lie horizontally when the patient is standing. Or it may be that, although the epididymis is closely applied to the testis, the structures of the lower part of the cord are loosely adherent to the epididymis and thus allow the horizontal disposition of the whole testicle. In this series the anomaly was always bilateral, and the general view seems to be that this is the rule.

The patients' ages ranged from eight to 30. The majority were teenagers; one was under 10, three were over 20. The right testis was affected in 11 patients, the left in five.

All the patients seen during an attack were febrile. Temperature ranged from 99° F within a few hours to 103° F later. In one patient abdominal pain and vomiting preceded other symptoms for a whole day, and appendicitis was suspected.

In all the 13 patients examined standing, the unaffected testicle could be seen lying horizontally. This sign could be clearly demonstrated even in cases with much scrotal redness and edema.

In only four of the 16 cases was the correct diagnosis suspected by the doctor who first saw the patient; eight were diagnosed as epididymitis; one was diagnosed as hysteria, one as appendicitis, one as spermatocele, and in one no diagnosis was offered. Moreover, seven were initially diagnosed and treated as epididymitis after admission to a surgical ward, for periods varying from a few hours to 14 days.

Regardless of fever, boys and young men with painful scrotal swellings, however inflamed these may look, should be examined standing up in spite of the additional pain this may cause. If the unaffected testicle is seen to lie in a horizontal plane, no diagnosis but torsion should be entertained.

STROKE TREATED SURGICALLY

Young et al. have reviewed 100 cases of extracranial cerebral vascular disease which they have treated surgically. In this group of patients the greatest percentage had artery occlusion in the carotid and vertebral arteries; a few, in the innominate and subclavian. In describing the symptoms the authors referred to remote stroke, progressive stroke, and acute stroke; whereas transient cerebral ischemia constituted 70 per cent of the group.

Physical examination revealed a difference in the pulse and blood pressure in the two arms; positive carotid compression was found in approximately 60 per cent of those tested. Incidentally, there was no fear of this test. The ophthaldynamometer findings correlated with the disease in approximately 50 per cent of the cases, but arteriography was considered to be the only dependable diagnostic method. In addition, the risk was very low.

In the treatment of these patients, 88 received endarterectomy. The best results were obtained in those who presented themselves with episodes of transient cerebral ischemia; it was found that in this group 90 per cent showed improvement.

It appears from this study that in a selected group of individuals presenting particularly transient cerebral ischemia, it should be worth while making studies and performing endarterectomy, which seems to offer considerable benefit. In this group none had subsequent symptoms.

STENOSES OF ARTERIES OF THE LOWER EXTREMITY

These authors demonstrated that patients with intermittent claudication due to stenosis of the arteries of the lower extremities may have pedal pulses at rest which disappear with exercise. By means of animal experimentation they demonstrated that the major artery to the lower extremity may actually be occluded, and yet there will be a collateral flow and pedal pulses distal to this. They performed intravascular arterial pressure studies in the animals. By artificially stimulating and exercising the lower limbs, they also demonstrated that the flow remains high but that the pulse of the arterial pressures decreases distal to the site of incomplete obstruction. If the obstruction reaches more than 75% of the cross-sectional area of the artery, there is not only a decrease in the pulse distal to the partial obstruction but also a decrease in flow.

They then took the laboratory study into the clinical application by recording the status of 16 patients operated upon, who had between 50 and 83% of the luminal diameter of the femoral arteries obstructed (amounting to 75-97% of the cross-sectional area). These patients had reconstruction of the artery by means of endarterectomy or by venous bypass. Prior to the operation exercise tests were performed on 11 of the patients. All patients prior to exercise had pedal pulses at rest. However, after exercise all the pedal pulses disappeared. After reconstruction of the operation this disappearance of the pedal pulses did not occur. Femoral arteriograms were obtained on four patients following operation which demonstrated patency to the artery. Of the 16 patients who had reconstructive surgery, 12 demonstrated significant improvement six to 66 months after operation.

Continued

The authors concluded that the disappearance of the pedal pulses in a proximal partial constriction is primarily an exaggeration of the normal hemodynamic response, rather than a vasospastic response. The vasodilatation that accompanies exercise decreases the peripheral resistance to increased flow through the major arteries. The decreased peripheral resistance is believed to be in vessels in the large muscles of the leg proximal to the constriction. The authors also felt that the critical stenosis for the human femoral artery appeared to be between 75 and 97% constriction of the cross-sectional area. Patients with such a constriction had loss of pulses and no relief of claudication following lumbar sympathetic block or lumbar sympathectomy following exercise.

This is a rather nice clinical and experimental study. The authors substantiate that the presence of pedal pulses at rest does not necessarily rule out a constrictive lesion at a femoral artery. Indeed from this study, the necessity to exercise the patient and then check the pulses is evident. They also reiterate that, should patients have a complete obstruction with collateral flow and pulsation, obstruction may precipitate problems of ischemia distal to the block. It has been shown by other studies that one of the problems in people who have partial obstruction is that complete thrombosis at the obstruction may occur, with propagation of thrombi into the distal arteries and obstruction of the collateral flow. This lateral type of thrombosis may play a more important part in the resolving ischemia to the limb than the initial site of thrombosis.

VERDOGLOBINURIA

In a study of 15 burned patients dying of gram-negative septicemia, particularly of pseudomonas, an urinary pigment- Verdoglobin- was found to be excreted in the urine. The assumption is that the pseudomonas toxin inhibits the reticuloendothelial system from continuing the degradation of hemoglobin into bile-pigment, and that at this stage failure in the continued process allows for buildup and thus urinary excretion of this intermediate pigment. The authors found that the use of fluorescent light many days prior to its recognition in ordinary light permitted advance recognition of this most ominous sign in septicemia. The authors hope that this may be a sufficiently early sign to treat the pseudomonas infection adequately before irreversible damage from the gram-negative septicemia occurs.

This is an interesting observation, and may well be an addition to the constant search for methods of salvage of the extensively burned patient.

CHEMOTHERAPY IN INFECTIONS OF THE URINARY TRACT

In a one-year study of 110 patients with urinary tract infections it was found that the patients could be sorted out into four main categories, and that the chief factor in determining the outcome was not the type of therapy but the category in which the patient fell. The diagnostic categories were: (1) Uncomplicated acute pyelonephritis; (2) Complicated acute pyelonephritis (infection with obstructive uropathy); (3) Known chronic bacteriuria (mostly E. coli, but also klebsiella aerobacter, paracolon, and P. mirabilis); and (4) Asymptomatic bacteriuria of unknown duration. In the first category, consisting of women infected with E. coli sensitive to all antibiotics, response to therapy was good. Members of the second category responded well to therapy when the obstructive factor was removed. In the third category, the bacteriuria was eliminated during therapy but recurred, either with the same pathogen or a different one, when therapy was stopped. In the fourth group, mostly females, responses were similar to group 3.

There were 37 females and 73 males, only 12 of whom were under thirty years old. Of the rest, 48 were over sixty-nine; 34 were between fifty and sixty-nine; and 16 between thirty and forty-nine. By table, the authors relate age and sex to the diagnostic category. Drugs used in this series were streptomycin, sulfonamides (not specified), tetracycline, chloramphenicol, kanamycin, and polymixin B. The patients were classified and the bacterial resistance encountered tabulated by diagnostic categories. The clinical response of each patient was studied in relation to antibacterial response.

In groups 1 and 2, only one bacterial strain out of 19 was found resistant (to sulfonamide only). No strain was resistant to any of the other drugs used. Group 3: Known Chronic Bacteriuria (20 strains). In this group six strains were resistant to streptomycin; 14 to sulfonamides; six to tetracycline; and one to chloramphenicol. Group 4: Asymptomatic Bacteriuria (78 strains). In this group 12 strains were resistant to streptomycin; 22 to sulfonamides; 10 to tetracycline; and two to chloramphenicol. All strains, however, were sensitive to kanamycin and all but three to chloramphenicol.

All patients improved symptomatically regardless of therapy or bacteriologic response. Most were free of symptoms in a few days despite persistence of bacteriuria. Only patients suffering gross obstruction and impaired drainage of urine failed to show prompt clinical improvement. The febrile response was also found to be independent of bacterial response as gauged.

The immediate bacteriologic response, unlike the clinical response, was plainly related to the sensitivity of the initial pathogen to the antibiotic administered to the patient. Regardless of the initial effectiveness of the antibiotic against the bacterial offender, however, the final outcome was a function of the diagnostic category of the patient, rather than bacterial sensitivity to the drug.

Lindemeyer, Robert, Petersdorf, Robert: Ann Int Med 58:201, 1963.

After all, the two most important things to learn are, where to find the knowledge you need, and how to get along without it. — Nuggets

Are you as proud of American research as you should be?

Where do the modern drugs you prescribe come from? Between 1941-1964, there were 604 different, new chemical entities made available as drugs to physicians throughout the world. About 74% of these came from the research laboratories of three of the four countries below. If you haven't already done so, take the little quiz.

Now, ready? The answers may surprise you. The United States led all the rest with an amazing total of 369 drugs; Switzerland was next with 44, and Germany next with 33. Italy, a country without patent protection for the inventor, had 0. That's a research score Americans can well be proud of.

research quiz For two decades, three of these four countries have led the world in drug research. Of the 604 significant drugs discovered in the world during this period, how many do you think came from each country? (Answer above)

☐ SWITZERLAND

☐ ITALY

☐ GERMANY

☐ UNITED STATES

Book Reviews

Books are masters who instruct us without rods or ferules, without words or anger, without bread or money. If you approach them, they are not asleep; if you seek them, they do not hide; if you blunder, they do not scold; if you are ignorant, they do not laugh at you. — Richard de Bury

PROCEEDINGS OF THE WORLD FORUM ON SYPHILIS AND OTHER TREPONEMATOSES — **U. S. Department of Health, Education and Welfare, Public Health Service, PHS Publication No. 997, Government Printing Office, Washington, D. C., 1964.**

The World Forum on Syphilis and Other Treponematoses was convened in Washington, September 4-8, 1962, to exchange information and ideas which would be useful in the world-wide struggle to eradicate these infections. As the Foreword points out, the 1500 delegates from over 50 nations included many of the world's authorities on the treponematoses. The Proceedings include scientific papers by specialists on the medical, administrative, and behavioral aspects of venereal disease-control programs.

Since 1958 there has been an alarming increase in the incidence of infectious syphilis in Minnesota as well as all parts of the nation. The problem is expected to continue for the next decade at least, as a result of the 38 per cent population explosion of the young adult age groups. For these reasons, the authoritative articles on such medical aspects as the clinical use of laboratory tests, the problems of biologic false positives, the treatment of early syphilis and the handling of penicillin-allergic reactions are welcome.

A long list of articles on the behavioral sciences related to venereal disease control gives interesting insight on the people concerned with these diseases.

This is a big book which provides a valuable landmark. Copies have been placed in several medical society libraries and the volume can be borrowed from the State Health Department.

PATIENT CARE AND SPECIAL PROCEDURES, SECOND EDITION — **By Venes and Watson, C. V. Mosby Co., 1964; 228 pages, price $6.25.**

This book is written collaboratively by an experienced nurse and an x-ray technologist for the x-ray technology student. It is an excellent, concise presentation of the more specialized procedures with which the x-ray technologist is involved and the associated rudiments of nursing care with which he must be familiar. The sections dealing with the various categories of emergency and special care patients are particularly pertinent. This book should be read by every x-ray technology student and should be available in the library of every school of x-ray technology.

C. N. Hess, M.D.
Minneapolis, Minnesota

THE OBSTRUCTING ACROMION — **Bernard Diamond, M.D., F.A.C.S., Charles C Thomas. No price listed.**

This is a short (207-p.) monograph on a rather limited orthopedic subject.

The author proposes that resection of the acromion through a proper approach is instrumental in the surgical correction of the following shoulder problems: calcific tendinitis; chronic ordinary cuff tear, chronic massive cuff rupture; lesions of bursa, biceps, and supraspinatous tendons; after fractures of the greater tuberosity.

His impressions are based on his own personal experience with 44 operated cases in which he certainly has achieved remarkably good results.

The book should be of interest to orthopedic surgeons.

Information and Orders Are Vital

WILFORD E. PARK, M.D.*
Minneapolis, Minnesota

IN THE modern concept of treating the whole patient, through the ministrations of a team of medical and paramedical personnel captained by the attending physician, the nurse still plays a key role. Aside from the physicians and specialists directing the patient's care, no one needs to be better informed than the attending nurse. In this paper we are concerned with the nurse's need to know her patient as quickly and as completely as possible. The "Patient Care Referral" discussed in this paper is designed to facilitate transmission of vital information to her.

The Patient Care Referral form (see front and back illustrations) was developed in Minneapolis in the latter part of 1963 by a committee organized for the purpose as part of a Demonstration Project supported in part by U.S. Public Health Service funds under Contract No. PH 86-62-80 with the Minneapolis Health Department. Since use of this form is rapidly extending throughout the State, every practicing physician and nurse in Minnesota should be familiar with its structure, purposes and potential. The form performs its major service as a communication tool[1] when the patient is being transferred and, therefore, passes from the care of one nurse or nursing service into the hands of another nurse or nursing service. The Patient Care Referral serves equally well regardless of the direction of the transfer and regardless of the diagnosis.

The portion of the form requiring the doctor's attention is on the front, in section III. It is so designed that the attending physician need not write much, but what is written is of great importance to the nurse and vital to the care of the patient. The diagnosis is, of course, a must. Sometimes more than one is indicated. The diagnosis should be specific with dates, such as "Right hemiplegia was aphasia on July 10, 1964."

---

*Director Adult Health, Minneapolis Health Department.

Continued

In some instances past medical history is important. The check list of disabilities enables the physician to indicate common impairments without extensive writing. The doctor's "Orders for Active Care" are not orders for physical therapy; these are orders for nursing to be carried out with the same diligence as giving medicines.

The modern concept of nursing incorporates the philosophy that retention of self-respect and personal dignity and even the will to live are somehow bound up with a patient's ability to take care of himself and to participate in activities with other people. In this concept, nursing does not mean turning away from tender loving care, when it is needed, but it does mean turning its back on coddling, pampering, and fostering of self-pity. The emphasis on patient activity inherent in "active nursing care" gives to the practice of medicine a dynamic revitalizing element which may make the difference between dependent chronic invalidism and a self-sufficient satisfying retirement.

"Active nursing care" is not physical therapy practiced by nurses, and it is no substitute for physical therapy, but it is a supporting role of nursing which may be the sustaining factor making the difference between success and failure in the team approach of physiatrist, nurse and physical therapist. Active nursing-care activities carry with them certain inherent risks which the attending physician is in the best position to evaluate. It is therefore imperative

that the physician specify when and how much should be undertaken. This is part of the physician's responsibility to prescribe what is best for his patient, but it also defines for the nurse those practices and activities which the doctor is prepared to stand behind and to share legal responsibility for.

The usefulness and success of the Patient Care Referral form is dependent upon the willingness of persons participating in the care of a patient to pass on their knowledge and experience with an individual patient to another physician, nurse, or institution to whom the patient is sent. Physicians and nurses in Minnesota have the first opportunity to prove the worth of this communication tool and through it to demonstrate the high quality of care that can be sustained when a patient passes from one institution or nursing service to another.

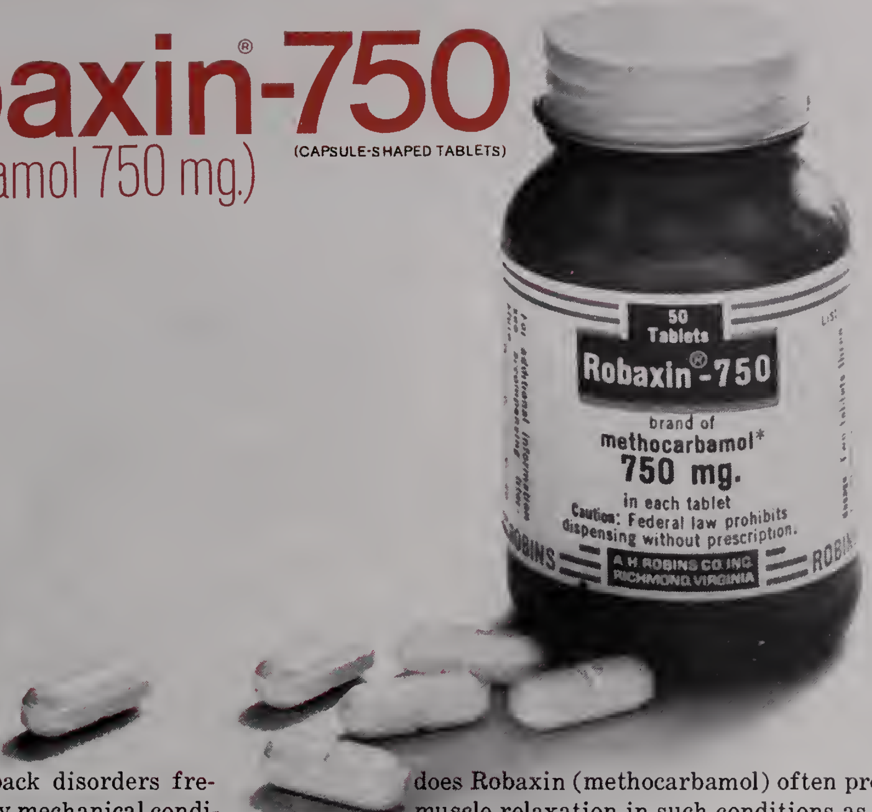
and Robaxin®-750

(methocarbamol 750 mg.)

(CAPSULE-SHAPED TABLETS)



It has been noted that low-back disorders frequently "...are caused by truly mechanical conditions which yield to conservative treatment."[1] Basic to this conservative treatment are bed rest, a board for the bed, and applied heat. In addition, a good muscle relaxant is often helpful, as "...muscle relaxants are useful in chronic as well as acute low backaches."[4]

Robaxin (methocarbamol) has relieved spasm and pain in cases where the patient "had not responded to conservative measures prior to drug therapy."[6] A 100-patient study showed that Robaxin provided greater relief of muscle spasm for a longer period of time without adverse reactions "than any other commonly used relaxants...."[6]

A well-tolerated[7] skeletal muscle relaxant with "specificity of action,"[7] methocarbamol leaves normal muscle tone unaffected. Moreover, there is little likelihood of sedation[7]—a considerable advantage for the patient who must remain active and alert on his job.

Significantly, clinicians advise using a muscle relaxant "early and in adequate dosage."[8] In this regard, Robaxin (methocarbamol)—*particularly in the 750 mg. dosage (2 tabs. q.i.d.)*—offers optimal therapeutic benefits without a significantly increased incidence of side effects. And just as it works well as part of the basic regimen for low-back pain, so also does Robaxin (methocarbamol) often provide muscle relaxation in such conditions as musculoskeletal injury, chronic neurological disorders, and orthopedic situations.

BRIEF SUMMARY—Robaxin (methocarbamol) Tablets: Contraindicated in hypersensitive patients. Side effects (light-headedness, dizziness, drowsiness, nausea) may occur rarely, but usually disappear on reduced dosage. Hypersensitivity reactions develop infrequently.

ALSO AVAILABLE: Robaxin® Tablets (methocarbamol, 500 mg.) Robaxin Injectable (methocarbamol, 1 Gm./10 cc.)

Robaxisal® (methocarbamol with aspirin) and Robaxisal-PH Tablets (methocarbamol with Phenaphen®).

History of Medicine

William Beaumont

(Continued from April issue, page 535.)

Although the English physician, William Prout, demonstrated in 1823 the existence of free hydrochloric acid in the stomach and showed that the presence of this acid was necessary for gastric digestion, it was Beaumont who brought the actual process of solution of food into the range of medical practice. This prototype of the true scientific spirit accurately recorded the movements of the stomach during digestion.

The influence of the emotions on the motility of the digestive tract has been known from time immemorial, as instanced in Shakespeare's Othello: "The thought thereof doth, like a poisonous mineral, gnaw my innards," and shown in the Bible: "Joseph made haste, for his bowels did yearn upon his brother." Gen. 43:30. This was only casual observation, but the actual fact of the effect of the psyche on salivary, gastric, and pancreatic secretions was first demonstrated by Beaumont.

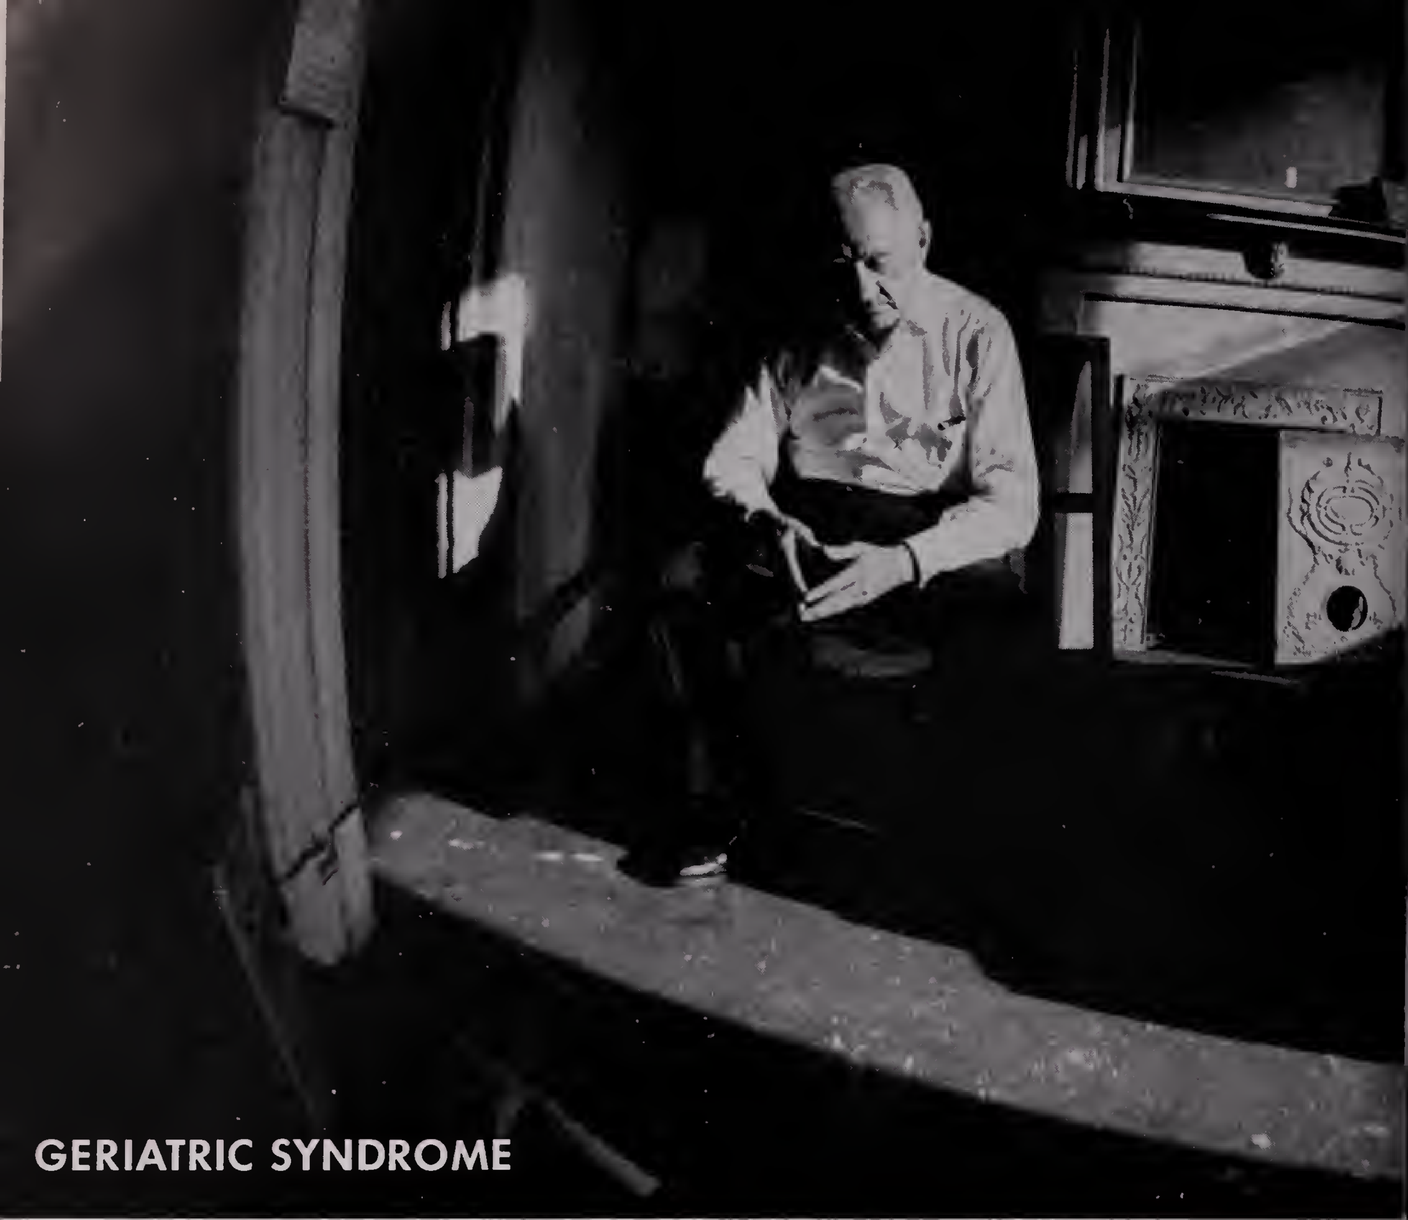
In 1824 Beaumont sent a complete report of his case to Surgeon-General Lovell, who encouraged him to continue his work.

St. Martin was a most recalcitrant human guinea pig. He grew tired of Beaumont's experiments on him, and would run away for long periods of time. The relations between the persistent doctor and his irresponsible subject constitute some of the most amusing episodes in early medical Americana. Many times when Beaumont wished to retrieve the roving St. Martin, he would enlist the aid of officials of the American Fur Co. Correspondence between Beaumont and these officials show the esteem in which he was held and how anxious these men were to help him continue his work. Since the bulk of Beaumont's experiments were completed at Prairie du Chien, names familiar to our region such as Hercules L. Dousman, Ramsay Crooks, and General Henry H. Sibley appear.

"The indomitable experimenter, having now carried out his observations on gastric digestion for eight years, decided to publish a book summarizing his work, and, in 1833 EXPERIMENTS AND OBSERVATIONS ON THE GASTRIC JUICE AND THE PHYSIOLOGY OF DIGESTION by William Beaumont, Surgeon, U.S.A., was printed at Plattsburgh. This work is a classic in physiology. The author described clearly the appearance and properties of gastric juice, proved that the active acid in the gastric juice is hydrochloric acid, pointed out that gastric juice and mucus are separate secretions, demonstrated the profound influence of mental disturbances upon the secretion of the gastric juice, and carried out the first study on gastric motility. He studied further the digestibility of various foods, work which remains today one of the greatest contributions to the subject of dietetics."[5]

Beaumont died in St. Louis April 25, 1853, where he had been in practice since 1839. Shortly before he passed away he uttered these immortal

Continued to page 678



when a change in environment overwhelms him with anxiety

Failing health, financial difficulties, or the death of a spouse are among the reasons why elderly people may be obliged to leave their familiar surroundings. Moving in with children or entering a home for the aged may satisfy practical requirements but can be psychologically traumatic since emotional resilience tends to diminish with age.

Even when anxiety reaches overwhelming proportions, you can counteract it promptly with the potent tranquilizer—Atarax (hydroxyzine HCl).

The outstanding systemic safety record of Atarax makes it particularly suitable for geriatric patients whose drug tolerance is often low. The usual initial dosage in such patients is 50 mg. q.i.d. However, this tranquilizer is so well tolerated that dosage can be adjusted to meet individual requirements. The wide variety of dosage forms allows flexibility of administration from any standpoint—convenience, patient preference, or emergency requirements.

No age, of course, is exempt from anxiety and any number of circumstances can unleash it. Keep Atarax in mind for *all* your emotionally distressed patients—from under 6 to over 60.

for any age—for any stage of anxiety

Rx ATARAX®

Division, Chas. Pfizer & Co., Inc.
Science for the World's Well-Being®
New York, New York 10017

Side effects and precautions: The transitory drowsiness which may occur with hydroxyzine HCl usually disappears spontaneously in a few days with continued therapy, or is correctable by dosage reduction. Dryness of the mouth may be seen with higher doses. Involuntary motor activity has been reported in hospitalized patients on higher than recommended doses. Hydroxyzine HCl may potentiate CNS depressants, narcotics such as meperidine, barbiturates, and anticoagulants. In conjunctive use, dosage for these drugs should be decreased. Because drowsiness may occur, patients should be cautioned against driving a car or operating dangerous machinery. **Parenteral Solution Precautions and contraindications:** This dosage form is intended only for I.M. or I.V. administration and should not, under any circumstances, be injected subcutaneously or intraarterially. When the usual precautions for I.M. injection have been followed, reports of soft tissue reactions have been rare. I.V. administration should be slow, no faster than 25 mg. per minute, and should not exceed 100 mg. in any single dose. Particular care should be used to insure injection only into intact veins; a few instances of digital gangrene occurring distal to the injection site have been attributed to inadvertent intraarterial injection or periarterial extravasation, both of which should be avoided. **More detailed professional information available on request.**

Sir Astley's Daily Schedule

A day in the life of Sir Astley Cooper (1768-1841) was fully as exacting as a day in the life of John Hunter. According to Bransby Cooper, he rose at six, even in winter, dissected until half-past seven or eight, when he had his hair dressed (he wore it powdered with a queue). Then at half-past eight he began to interview his free patients. His breakfast consisted of two rolls, followed by a quick glance at the newspaper. After that he received patients in his consulting room until one. (His servant Charles gave gentlemen preference over ladies, whose time he rated as of little importance; but he could be bribed.) At one o'clock Sir Astley left in his coach, sometimes going out of the house by the back door in order not to run the gauntlet of the disappointed and irate patients still waiting to see him. A very different atmosphere awaited him at Guy's. The steps would be thronged with as many as 100 persons — apprentices, students, hospital staff — who would greet him with great animation and jostle for his recognition. The cavalcade would then tour the wards, Sir Astley courteously explaining any interesting cases. Next he would go to the operating theatre to lecture for perhaps an hour, then out by way of the dissecting room to tour his professional circuit until half-past five or later. After dinner he might fall asleep for ten minutes, but often he would set off again to the hospital to deliver another lecture or to address a medical society. He would be home again by midnight. It was a great day for a great man, who did not conceal that he enjoyed his popularity.*

Gossip is vice vicariously enjoyed. — Elbert Hubbard

Rural Medical Scholarship

State Physicians Award Rural Medical Scholarship

David Arthur Pope, a University of Minnesota Medical School freshman from Janesville, Minnesota, has been named recipient of the Minnesota State Medical Association's 1964-65 Rural Medical Scholarship.

This $4,000 scholarship, awarded annually to an outstanding freshman medical student, provides $1,000 a year for each of the four years of medical school. In agreement with the terms of the scholarship, Pope has agreed upon completion of his training to practice medicine for at least five years in a rural Minnesota community in need of a physician.

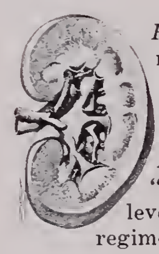
In announcing the award, Dr. Charles G. Sheppard, St. Peter, Minnesota, chairman of the Association's Scholarship and Loans Committee, said the purpose of the scholarship, which originated in 1952, is to provide financial assistance to worthy and outstanding students, and insure a continuing supply of physicians for non-metropolitan areas of Minnesota.

Pope is the fourteenth student to receive the Association's Rural Medical Scholarship. Previous recipients currently practicing in rural Minnesota communities include: Dr. Leland Christenson, Maple Plain; Dr. Myron Doebler, Mora; Dr. Carl Christenson, Clinton; Dr. Vincent Hunt, Red Lake Falls; Dr. LeRoy Mueller, Hendricks: and Dr. George B. Gerstenkorn, Milaca. Dr. Donald Asp, Milaca, is currently completing his internship.

Scholarship winners still attending the University of Minnesota Medical School are Charles Benjamin, Hutchinson; Elton Wing, Jackson; Roland Roy Larter, Lancaster; and William J. Norberg, Barnum.

David Arthur Pope, a University of Minnesota Medical School freshman from Janesville, Minnesota, has been named recipient of the Minnesota State Medical Association's 1964-65 Rural Medical Scholarship.
He is the son of the Rev. and Mrs. W. E. Pope of Lafayette, Minn.

One antibiotic superior to
Tetracycline
Chloramphenicol
Streptomycin
Kanamycin
Polymyxin B
Penicillin G
against Proteus mirabilis and E. coli



Proteus mirabilis is not only the most common cause of *Proteus* infections of the urinary tract, but such infections are often resistant to other antibiotics.[1-4] According to Anderson *et al.*,[5] "When assessed in terms of serum levels attainable with usual dosage regimens, ampicillin was the most effective drug tested against *E. coli* and *P. mirabilis.*" These authors found *Klebsiella-Aerobacter* and *Pseudomonas* organisms relatively insusceptible to ampicillin. With its broad-spectrum coverage of many gram-positive and gram-negative bacteria, absence of toxicity, and slow emergence of resistant strains, PENBRITIN (ampicillin) is a most beneficial and safe drug in treating urinary tract infections—*killing* the pathogens, not just suppressing them.

Dosage: Adults—500 mg. every six hours (higher doses may be required for severe infections). Children—(under 13 years, whose weight will not result in a dosage higher than that recommended for adults) 100 mg./Kg./day in divided doses every six or eight hours for moderately severe infections; 200 mg./Kg./day in divided doses every six hours for severe infections.

Contraindications: (1) Hypersensitivity to penicillin. (2) Infections by penicillinase-producing staphylococci and other penicillinase-producing organisms. *Aerobacter acrogenes*, *Pseudomonas pyocyanea*, and *Proteus morganii* are resistant to PENBRITIN (ampicillin).

Side Effects: Mild effects, such as skin rashes, diarrhea, nausea and vomiting, have occasionally appeared.

Precautions: As with other antibiotics, precautions should be taken against gastrointestinal superinfection. To date, safety for use in pregnancy has not been established.

Supplied: No. 606—Each capsule contains 250 mg. of ampicillin. Bottles of 16 and 100.

Latin American Medicine

Observations of a World-Health Organization Fellow on a Study-Tour in Latin America

CLEMENT C. CLAY, M.D.*
New York, New York

ALTHOUGH A university professor usually cannot boast of great financial reward for his labors, there are certain compensating factors to be taken into consideration. One of them is the opportunity to travel and to study conditions which may assist him in the instruction of his students, American as well as foreign.

In every country we visited, there was an intense interest in the integration of preventive and curative services. In our country we give lip service to such a concept, but we have done relatively little about it. Admittedly the problem is different in countries where medical care is largely the responsibility of the government, as it is in Latin America.

Chile appears to have made the greatest progress in the integration of the services. There the National Health Service was established by law in 1952 to integrate under central government direction: "(a) the services of the voluntary hospitals serving both insured manual workers and indigent persons, (b) the medical services for blue-collar workers, provided principally through centers for care of ambulatory patients, (c) the total public health program with its health centers and stations for various preventive services, and (d) several smaller services.**"

In each Health Area, there are a Base Hospital and Intermediate Hospitals as well as outpatient services, and "Postas Medicas" located in small villages. The outpatient facilities provide all of the services necessary to keep patients *out* of the hospitals as much as possible.

Specialists

Specialists go from the Base Hospital in the Area Poniente in Santiago to the *consultorios* health centers. When a specialist goes to a consultorio, he may see patients as a generalist; but as a specialist he will later see those who are referred to his service at the Base Hospital.

Routine laboratory and X-ray work is done in the consultorios, but complicated procedures are referred to the Base Hospital. All physicians on the staff of the consultorios are on the staff of the Base Hospital. Each is assigned patients for whom he is responsible, and they consider him their doctor. He keeps their medical records in his office. The chief of each service in the Base Hospital must plan and execute the whole program (preventive and curative) for his service in the Area Poniente. He must visit the consultorios and the peripheral hospitals periodically.

The Medical School

San Juan de Dios is a teaching hospital for the Medical School of the University of Chile and the base hospital for the Area Poniente. The chief of each service is a Professor of

*Doctor Clay is Director of the Graduate Program in Hospital Administration at Columbia University and was Director of St. Barnabas Hospital in Minneapolis from 1939 to 1941 before going on active duty in the U. S. Naval Medical Corps in World War II.

**Quoted from "Medical Care in Latin America" by Milton I. Roemer, M.D.

the University; but not all of the physicians are on the faculty. Over 300 physicians are attached to the facilities in the Area Poniente (a few work two or three hours a day; most work four hours; some work six hours). There are 20 to 30 residents and 30 to 35 interns. Student nurses from the University have their practical work at the Hospital, and consultorios and laboratory technicians and social workers also come from schools outside the Hospital for practical experience. There is a nine-month course for auxiliary (practical) nurses.

Rural Areas

In the United States, as well as in Latin America, it is difficult to provide adequate medical care to people in the rural areas; physicians, nurses, and other professional and technical personnel are reluctant to leave the big cities. An interesting program has been developed in Colombia by the University of Vallee of Cali. In recognition of its responsibility for the health and welfare of the people in the rural areas, the University formed a committee in 1955 to study medical care needs. The State Government designated the University as the agency for providing complete preventive and curative health services to the people in the County of Candelaria, which has a population of 4700, chiefly Negroes. Most of the people work in the sugar industry, in fields or factories; but a few have shops in town. The average income is about 500 pesos ($50 U. S.) per month.

Throughout the State, all prospective mothers are entitled to prenatal care; preschool and school children are entitled to dental care; all inhabitants are entitled to environmental sanitary services. In Candelaria, however, *all* people are entitled to *complete* preventive and *curative* health services. They pay what they can for those services (50 pesos — $5.00 U. S. for a delivery, for instance). All deliveries in the hospital are done by M.D.s, but midwives do 50% in homes.

Sanitation

The project at Candelaria provides an excellent educational medium for medical students, residents, nurses, and other personnel. Presumably, however, some of those in training should be encouraged to make a career of caring for people outside the large cities. It would seem desirable for other medical schools in Latin America and elsewhere to take an interest in the health needs of the people in rural areas.

Mexico

In Mexico, the Ministry of Health and Welfare has many health centers; but a significant new development has been the creation of a Department of Public Health in the 2,000-bed General Hospital in Mexico City, whose spacious quarters provide rooms for cancer detection, communicable diseases and immunization, a routine chest X-ray unit, offices for the Chief and Assistant Chief and for twelve social workers, and a classroom for health education and other conferences.

The Latin American countries and the United States appear to have one problem in common: the difficulty of interesting the average physician in preventive medicine. Progress has therefore been delayed.

A Latin American "showplace" is the magnificent Centro Medico Nacional del Instituto Mexicano de Seguro Social, a new 2000-bed institution of the "blue collar" Social Security system in Mexico City. This is not truly a "Medical Center" in the sense that the term is used in the United States, but rather a group of seven separate Hospitals with certain supporting facilities. The buildings are handsome and many of them have huge bas-relief murals in stone on their outside walls. Inside, much marble and beautiful woodwork have been used, and there are colorful murals in the lobbies. The equipment is excellent. The facilities, however, are not quite so luxurious as those in the Hospital Central del Empleado in Lima.

Chile

In Chile, the National Health Services has adopted the wise policy of investing in personnel, rather than in buildings. The hospitals and consultorios are substantial structures which are functional but relatively free from frills. An attractive 400-bed general hospital about 55 miles from Santiago was nearing completion, its estimated cost between $1 and $1.5 million U. S. It has been well-planned and should function efficiently and require a minimal amount of maintenance. A comparable building in the United States would probably cost at least $10 million; but labor costs in Chile are far lower.

Peru

In Peru, there is a great contrast in the physical plant and equipment of the hospitals of the Ministry of Public Health, the "blue-collar" Social Security system, and the Beneficencia (somewhat comparable to our voluntary hospitals) on the one hand and, on the other hand, the palatial Hospital Central del Empleado of the "white-collar" Social Security system in Lima. "Stupendous" is a good word to describe this magnificent example of modern architecture. The grounds are beautifully landscaped and the direct approach to the main entrance is across a huge paved plaza. This colossal building with its fourteen stories above two basements is 300 meters long and has a vast expanse of glass. Marble, handsome woodwork, and live plants beautify the mammoth lobbies in the Hospital and Outpatient Department which occupies a one-story wing along with a large, beautiful auditorium. Everything in the building is over-sized. The corridors are nearer sixteen feet in width, rather than the usual eight feet. Each patient's room has only one or two beds and is larger than ordinary; each has its own shower, toilet, and lavatory.

There are about 2,000 visits a day to the medical and surgical clinics. The emergency service has six ambulances and about 180 patients a day. There are about 3,000 employees, including 278 physicians (working six hours a day), 68 interns, 34 dentists, one psychologist, 27 pharmacists, 617 professional and 478 auxiliary (practical) nurses, 113 midwives, and 120 student nurses. Because it is able to pay higher salaries and to offer such superb working conditions, the Hospital Central del Empleado would appear to have no difficulty in attracting physicians and other employees of the highest calibre.

Opportunity for Physicians

In Latin America, the physicians do not have the same reluctance to work for a salary that one observes in the United States. In the countries visited, most of them are employed at a salary for two, three, four, six, or eight hours a day. Because salaries are low, however, even those who work full time (eight hours a day) usually have a private practice in order to earn sufficient income. The consensus seems to be that the salaries are too low, but that there is little hope of their being increased substantially. Since so many of the people are provided with medical care at government expense, there are relatively few who pay for care as private patients. It must be difficult for a younger man to build up a private practice, since patients with the higher incomes are likely to select the well-known physicians.

In some countries young physicians are required to serve in rural areas for a period of time after graduation from medical school but they usually return to the large cities after fulfilling their obligation.

In each of the countries, the hospitals affiliated with medical schools appeared to have well-developed programs for residents in the various specialties. However, it was evident that physicians who could do so would go to the United States, to England, or to countries on the European Continent for postgraduate education.

Everywhere there appeared to be an earnest desire to make available good medical and hospital care to all of the people. The principal obstacles to the attainment of that goal are a great shortage of physicians, nurses, and other professional and technical personnel, the difficulty of correcting geographical maldistribution of available personnel, and a chronic shortage of funds to finance an adequate program of comprehensive health care and to improve nutrition and living conditions.

Don't let yesterday use up too much of today. — Brake Shoe Yardsticks

Of 341 patients with confirmed OB-GYN infections...
320 or 93.8% were treated successfully with Signemycin®

Note:

In 50 cases of serious puerperal and postabortal infections treated with Signemycin, complete cure was observed in 49 patients.* Duration of therapy ranged from three to eight days. Appropriate surgical measures were applied as indicated.

*Heredia Diaz, J. et al.: Medicina (Mex.) 38:308, July 10, 1958.

Condition	No. of Patients	No. Responded to Signemycin

In Minneapolis . . .

WHERE MINNESOTA DOCTORS WILL BE IN '65

Several innovations will mark the 112th Annual Meeting of the Minnesota State Medical Association which is scheduled for May 17 and 18 at the Minneapolis Auditorium.

One of them relates to a change in the customary schedule of the House of Delegates' meetings. The first session will be convened at 10:00 A.M. on Sunday, May 16, in accordance with a plan proposed by the Speaker of the House, Dr. John L. Falls of Red Wing, and approved by the Council at its February 28 meeting. Opening addresses and reports will be given at the morning session.

The change was occasioned by the fact that a special report must be considered by the full House this year, in accordance with a resolution adopted at the 1964 session. The Sunday afternoon session will take the form of general attendance at a meeting of the Reference Committee on Medical Economics Reports for the purpose of considering the special report.

Other reference committee reports, and the usual election of officers will take place at the final session on Tuesday, May 18 at 9:00 A.M.

The scientific sessions which open on Monday, May 17, will feature a far-ranging series of discussions and panels, all of them concentrated in two days of meetings. The two-day convention is another innovation tried for the first time this year, and it is the hope of the Committee on Scientific Assembly that attendance will be outstanding for both days of the meetings.

Monday's events include extensive discussions on the use of anticoagulants, on fractures in children, on functional disease and on alcoholism; also an important panel on medicine and religion.

Tuesday's program will be given by illustrious alumni and faculty members of the University of Minnesota. It will constitute the State Association's observance of the 75th anniversary of the founding of the Minnesota Medical School. Preceding the program, Dr. J. M. Stickney, President of the Association, will give a special tribute to Medical School accomplishments. Among the distinguished former Minnesotans who will speak are Dr. Raymond D. Pruitt, Chairman and Professor of Internal Medicine at Baylor University, Houston; Dr. George E. Moore, Director of the Roswell Park Memorial Institute, Buffalo, New York; and the Honorable Warren E. Burger, Judge of the United States Court of Appeals for the District of Columbia. Judge Burger will talk about the doctor in court.

Four and one half credit hours for each day have been approved for members of the Minnesota Academy of General Practice who attend.

Visiting speakers and local authorities will act as discussion leaders for five Round Table Discussion Luncheons on Monday and six luncheons on Tuesday, all at 12:15 P.M. at the Capp Towers Motor Hotel. Other special events will be the annual New Members, County Officers and Delegates dinner on Sunday, May 16, at 6:00 P.M.; a Fire-

side Conference on Chest Diseases on Monday night at 9:00 P.M., and the Annual Banquet of the Association which will be the final event and climax of the meeting, all at the Capp Towers. Entertainment plus the annual presentations will constitute the program.

Sports events begin at 10:00 A.M. on Sunday with the annual golf tournament at the Hazeltine National Golf Club in Chaska; and the annual skeet and trap shoot at the Twin City-Hopkins Gun Club. A sports dinner, open to all sports enthusiasts, will follow the play at the Hazeltine club.

The Annual Meeting of the Woman's Auxiliary to the Minnesota State Medical Association will begin at 9:15 A.M. at the Minikahda Country Club on Excelsior Boulevard. A program of reports, presentations and election of officers will be followed by the annual luncheon, also at the club, at which the national Auxiliary president, Mrs. William H. Evans of Youngstown, Ohio, will speak; and there will be an AMA-ERF pageant with Auxiliary members acting as models. The Tuesday program will be preceded, on Monday, by the Executive Board meeting at 10:30 A.M. at the Curtis Hotel, with luncheon; and the annual tea to which all doctors' wives are invited, to be held at the Lutheran Brotherhood Building in Minneapolis.

Programs for all meeting events have been mailed to all members and to physicians in surrounding areas. A large registration is expected and registration cards which went with the programs should be returned promptly.

Announcements continued from page 685

Postgraduate Courses at Vienna, Austria

The American Medical Society of Vienna in connection with the Vienna Academy of Medicine has available courses and seminars for practical medicine. Practical sessions and actual patient examination and treatment, surgical operations, round table discussions and grand rounds are part of these seminars. These seminars are arranged individually for any single visiting doctor or any group, for a few days or a month. Upon completion special certificates are issued for studies of three months duration. All these contacts are with English speaking members of the clinics. The cost of these courses range from $1.00 to $6.00 per hour for seminars, and up to $70.00 a month. Life membership in the Society is $30.00 and associate membership $10.00.

The club headquarters of the Society are situated in the University section of Vienna and in close proximity to the University Clinics. It offers every possible amenity to the visiting doctor. The club rooms and extensive library has become a study center for English speaking doctors in Europe. The visiting physician will find Vienna a revived cultural capital. The city surroundings are pleasant during all seasons. Water sports, golf, and during the winter all skiing and Alpine sports centers are within easy reach of the city. Hotel accommodations are available in all price classes to American standards. Time spent there under these auspices represents a bona fide medical continuation training and expenses incurred in connection with these seminars are deductible according to the Internal Revenue Service ruling.

Further information may be obtained by writing to the Secretary of the American Medical Society of Vienna, Universitaets-strasse 11, Vienna 1, Austria.

* * *

A symposium on Cardiac Emergencies will be held in the auditorium of the Ramsey County Medical Society, Lowry Medical Arts Bldg., St. Paul on June 4 and 5. No fee for registration. Open to all physicians. Laboratory Demonstrations will be included as part of course. Sponsored by Department of Medicine, Ancker Hospital, Minnesota Heart Association, State Health Department and St. Paul City Health Department. Contact: James Hammarsten, M.D., Ancker Hospital.

* * *

Three-day course directed to surgically oriented physician will be held at the University of Wisconsin's Medical Center, Aug. 26-28. Aspects of cardiovascular surgery, biliary tract surgery, general abdominal surgery will be presented. Write: The University in Madison.

* * *

Minneapolis Ophthalmological Society will hold a course in Practical Contact Lens Fitting, May 2, St. Barnabas Hospital School of Nursing in Minneapolis. Contact: Robert Fink, M.D., 1921 Medical Arts Bldg., Minneapolis.

The attempt to combine wisdom and power has only rarely been successful and then only for a short while. — Albert Einstein

SIGNEMYCIN®

Side Effects: Glossitis and allergic reactions, as well as severe anaphylactoid reactions, have been reported as rare side effects. Should significant reaction or idiosyncrasy occur, discontinue medication and institute countermeasures. Use of tetracycline during the last trimester of pregnancy, neonatal period and early childhood may cause discoloration of developing teeth. Reduce usual oral dosage and consider serum level determinations in patients with impaired renal function to prevent possible liver toxicity due to excessive accumulation of antibiotic in the serum.

Precautions: Overgrowth of nonsusceptible organisms may occur. In such cases, discontinue medication and institute appropriate specific therapy as indicated by susceptibility testing. Aluminum hydroxide gel given with antibiotics has been shown to decrease their absorption and is contraindicated. The coloring agents used in Signemycin Syrup and Pediatric Drops may produce red discoloration of stools.

Triacetyloleandomycin, a constituent of Signemycin, administered to adults in daily oral doses of 1.0 Gm. (3 Gm. Signemycin) for periods of more than ten days may produce hepatic dysfunction and jaundice. In the rare patient who requires this high dosage level of Signemycin initially, liver function should be carefully followed and dosage should be reduced, as promptly as possible, to the usual recommended range of 1.0 to 2.0 Gm. per day. Therefore, Signemycin is recommended primarily for the treatment of acute or severe infections, with treatment restricted to a ten-day period. If clinical judgment dictates continuation of therapy beyond ten days, serial monitoring of the liver profile should be carried out, including BSP, transaminase, and cephalin flocculation tests. Changes observed in liver function were reversible following discontinuation of the drug.

Formulas: Capsules: 250 mg. Signemycin (167 mg. tetracycline HCl and 83 mg. oleandomycin as triacetyloleandomycin).

Capsules: 125 mg. Signemycin (83 mg. tetracycline HCl and 42 mg. oleandomycin as triacetyloleandomycin).

Syrup: 125 mg. Signemycin (tetracycline equivalent to 83 mg. tetracycline HCl and 42 mg. oleandomycin as triacetyloleandomycin) per 5 cc.

Pediatric Drops: 100 mg. Signemycin (tetracycline equivalent to 67 mg. tetracycline HCl and 33 mg. oleandomycin as triacetyloleandomycin) per cc.

PFIZER LABORATORIES Division, Chas. Pfizer & Co., Inc. New York, New York 10017

®

Of 5,057 patients with confirmed infections of all body systems... 4,731 or 93.5% were treated successfully with Signemycin®

Note:

The high rate of response to Signemycin in these cases is noteworthy because the totals include many patients with difficult-to-treat infections, many whose infections had proved resistant to other agents, and many who had been treatment failures on other therapy.[1-87] In addition the following criteria were used for the cases cited: (1) only published results were used (2) results were confirmed by clinical and/or laboratory findings (3) patients were cured, not "improved" (4) dosage conformed with current recommendations in the United States (5) no other anti-infective agents were used concomitantly (6) no instance of prophylactic use was included in these tabulations.

Condition	No. of Patients	No. Responded To Signemycin
Ear, nose and throat infections	507	465
Respiratory infections	1,028	954
Gastrointestinal infections	425	387
Genitourinary infections	748	684
Skin and soft-tissue infections	1,088	1,036
Bone and joint infections	71	64
Deep-seated or generalized infections	257	251
Obstetrical & gynecological infections	341	320
Miscellaneous conditions	592	570
Totals	5,057	4,731 (93.5%)

consistently effective...often when others fail

AMA NYC 1965

June 20-24, 1965
114th Annual Convention

Come to New York City June 20-24. Be part of tomorrow's medicine and participate in the year's most extensive scientific meeting.

The excitement of America's largest city is available to you at the best time of the year, as you relax and review—in air conditioned comfort—the most recent developments in general practice and all the specialties.

- Six general scientific meetings
- 23 medical specialty programs
- 700 scientific and industrial exhibits
- Lectures, panel discussions, motion pictures and color television

Plan to attend—continue your postgraduate education.

See JAMA May 10 for complete scientific program—forms for advance registration and hotel accommodations.

Medical Economics

Give Yourself Ample Time

In recent years, great emphasis has been placed upon the importance of one's having adequate capital for income at retirement age. Too little importance, however, has been attached to the achieving of a degree of financial independence in advance of retirement age. This is a grave error.

The years between 45 and 64 have become the truly critical ones in a man's financial life. The young man in his thirties who fails to start saving and investing, contenting himself with the notion that there still is "plenty of time," is operating under a grave delusion. Facts indicate that if the "average" person has not accumulated a reasonable amount of capital by age 45, he is unlikely ever to do so. He has started his search for financial security at too late an hour, and the odds are strongly against his gaining sufficient momentum to make up for lost time.

There are two reasons for believing that a man must begin saving and investing early. One is pure arithmetic, and the other reflects the economic and psychological influences under which we live. The arithmetic is simple. We all know that a dollar saved today is worth considerably more than a dollar that we may save 20 years in the future. Today's dollar, invested wisely, will earn more dollars as the years go by.

Investments that will Accumulate to $1,000 at Age 65

(Assuming a 5% compound interest factor)

$142	invested at age	25
$181	invested at age	30
$231	invested at age	35
$295	invested at age	40
$377	invested at age	45
$481	invested at age	50
$614	invested at age	55
$784	invested at age	60

Stated another way, $181 invested at age 30 will grow to $1,000 at age 65, assuming a five per cent increment. The same $181 invested at age 50 will grow only to $375. If invested at age 60, it will grow merely to $232.

It is obvious from these figures that one dollar invested at age 30 will accomplish as much as two dollars invested at age 45, and as much as nearly $4.50 invested at age 60. As the rate of return and appreciation goes up, the value of early investing is magnified.

The greatest allies a man has in the capital-building process are (1) time and (2) return on capital. Both must work for him if he is to accomplish his financial goals. Take away time, and capital is denied the opportunity to grow. If the burden is placed upon capital — i.e., if too little money must achieve too much too soon — disproportionate risks must be undertaken.

Take away yield, the opportunity to invest productively — and only a very few men could set aside enough from their earnings to achieve any degree of financial independence. It is capital at work, not men at work, that brings eventual financial independence. True, men must work and save in order to provide the basic capital, but afterwards, the degrees of financial independence they attain will be directly proportional to the time that remains for the capital to grow.

Let's call a spade a spade! Can any man say that he is financially successful, whatever his income from his profession, when he has little or no income to report on page 3 of his Federal Income Tax Return? A man of 45 should be well on his way toward accomplishing his financial objectives — not just starting his pursuit of them.

The individual who contents himself with resolving to start his investment program *after* he finishes equipping his home luxuriously, *after* he has paid for his children's education, and *after* he has toured Europe and realized his other recreational dreams, is due for a rude awakening. Both time and simple arithmetic are building up strong odds against him.

The ingredients for success are an early start and tenacity in carrying out one's plan. These things will assure accomplishment; complacency and postponement will assure failure.

Delay

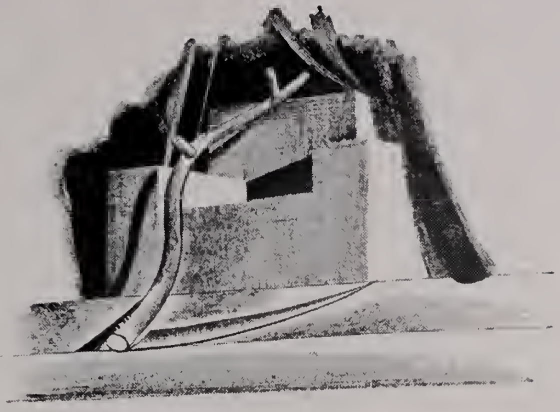
He slept beneath the moon,
He basked beneath the sun;
He lived a life of going-to-do
And died with nothing done.
— *James Albery*

Breast cancer can be highly curable if it is detected early, through regular examinations. Yet, despite all efforts in cancer education and improvements in treatment techniques in the last 30 years,

THE NUMBER OF BREAST CANCER DEATHS PER 100,000 WOMEN IN THIS COUNTRY HAS NOT DECLINED.

While research continues to seek new answers, it is imperative that greater efforts be made to detect breast cancer early and to get women to their doctors when chances of cure are best. That's why the American Cancer Society is encouraging its Divisions across the country to carry out special breast cancer educational programs. Newest of these are demonstration projects in which physicians in a community volunteer one day to giving breast examinations and to teaching hundreds of women breast self-examination. Breast cancer is one of the major cancer problems which we face and which together, doctor, we must try to resolve through intensified research and educational efforts.

AMERICAN CANCER SOCIETY



In Memoriam

What a superlatively grand and consoling idea is that of death! Without this radiant idea, this delightful morning star, indicating that the luminary of eternity is going to rise, life would, to my view, darken into midnight melancholy.

—John Foster

J. LAWRENCE NOBLE

Dr. J. Lawrence Noble, 56, St. Paul physician and surgeon, died at his home, March 7th. He was born in St. Paul and attended the University of Minnesota medical school.

Dr. Noble was a member of the American Medical Association, Minnesota State Medical Association, Ramsey County Medical Society, American Academy of General Practice, Bethesda Lutheran hospital staff, and was on the board of managers of the Bethesda infirmary. He was president of the Gustavus Adolphus church council, member of the board of trustees of the Gustavus Adolphus church and treasurer of the board of social ministry of the Minnesota Synod of the Lutheran Church in America.

He is survived by his wife, a son and a daughter.

CARL A. WITHAM

Dr. Carl Albion Witham, 83, Edina surgeon, died March 10th. He was born in Glouchester, Maine and graduated from the University of Minnesota medical school.

Dr. Witham practiced medicine for sixty years and was an honorary staff member at Methodist hospital and an active staff member at Lutheran Deaconess hospital. He was a member of the Hennepin County Medical Society and American Medical Association and a life and 50 Club member of the Minnesota State Medical Association.

He is survived by a daughter and two sons.

LOUIS A. NELSON

Dr. Louis A. Nelson, 89, long-time St. Paul physician, died March 10th. He was born at Lanesboro and had been a St. Paul resident for eighty-five years. Besides his own medical practice, Dr. Nelson was eye surgeon for the Northern Pacific Beneficial association for forty-two years.

He graduated from the University of Minnesota medical school in 1896 and was a member of the American Medical Association, Ramsey County Medical Society, life member of the American Academy of Ophthalmology, and a 50 Club member of the Minnesota State Medical Association.

He is survived by his daughter, and a son, Dr. Louis Nelson, Jr. of St. Paul.

DAVID M. SIPERSTEIN

Dr. David M. Siperstein, 67, Minneapolis pediatrician, died March 11th. He was an associate professor of pediatrics at the University of Minnesota and chief of staff of pediatrics at Mt. Sinai hospital.

Dr. Siperstein was a member of the American Academy of Pediatrics, the Minnesota Pediatrics Society, Minnesota State Medical Association, American Medical Association, Hennepin County Medical Society, Alpha Omega Alpha and Sigma Psi scientific societies.

He is survived by his wife and two sons, one of whom is Dr. Marvin D. Siperstein of Dallas, Texas.

ĕth´ĭks

Ethics. Where have they gone?

Ethics, says the dictionary, is "the science of human duty; moral science."

In today's world, so complicated with gadgetry and machines that we often lose sight of others and of our own best selves, it isn't always easy to keep "human duty" in mind.

As life gets more complicated, men lose their sense of identity, value and purpose. Life, in a sense, becomes "cheap" and "unimportant." And with that, it becomes ever easier to take the easy way, to ignore the principles of right—and our human duty to others.

The one place where human values are kept in proper focus is where you worship. Nowhere is the individual more valued. *And if you care*, the place where you worship can become, with your help, a rallying point for lifting all the deteriorating values you see around you. Worship this week—and put your faith to work *all* week.

Worship this week

RELIGION IN AMERICAN LIFE

Published as a public service in cooperation with The Advertising Council and Religion in American Life

Physician's Diary

It is good discretion not to make too much of any man at first, because one cannot hold out in that proportion.—Bacon

Dr. W. G. Workman, 77-year-old Tracy resident and civic leader and practicing physician for more than a half century, has been named "outstanding senior citizen" of Lyon County by a selection committee. **Dr. M. A. Burns**, 90-year-old Milan physician, was named "outstanding senior citizen" of Chippewa County. These gentlemen competed against entries from other counties in the state to name the State of Minnesota's "outstanding senior citizen."

* * *

On January 29, 1965 a group of physiatrists met in Minneapolis to form the Minnesota Physiatric Society. Elected as officers were: **Dr. Bror S. Troedsson** of Minneapolis VA Hospital, president; **Dr. G. Keith Stillwell** of the Mayo Clinic, vice president; and **Dr. John E. Quast** of the Minneapolis VA Hospital, secretary-treasurer. The purposes of the organization are to promote optimal care for physiatric patients, to further education of physiatrists and affiliated groups, and to encourage research in areas of interest to physiatrists.

* * *

The following physicians were recently certified as Diplomates of the American Board of Pathology: **Drs. Wayne A. Chadbourn, Robert L. Strom** and **Patrick C. J. Ward** of Minneapolis; **Dr. Richard P. Lynch** of St. Paul; and **Dr. Mehdi Orandi** of Fergus Falls.

* * *

At the recent meeting of the Minnesota Radiological Society, the following officers were named: **Dr. L. Fink** of St. Paul, president; **Dr. Joseph Jorgens** of Fort Snelling, vice-president; and **Dr. Edward A. Peterson** of St. Paul, secretary-treasurer.

* * *

Dr. L. H. Rutledge of Detroit Lakes has received special recognition for his achievements by being named in the 1964-65 edition of "Who's Who in the Midwest." **Dr. Henry Alexander Korda**, physician and surgeon at Pelican Rapids, was also named for this honor.

Dr. Mathew Yelle was recently given the Distinguished Service award by the Anoka Junior Chamber of Commerce, and **Dr. Arnold S. Leonard** was the winner of the Golden Valley Jaycees Outstanding Citizen award.

* * *

The medical staff of Fairview hospital, Minneapolis, elected in March **Dr. Robert R. Cooper** hospital chief-of-staff. Other officers elected were **Dr. M. S. Belzer**, chief-of-staff-elect; **Dr. John Hartwig**, secretary; and **Dr. Henry Brand**, treasurer.

* * *

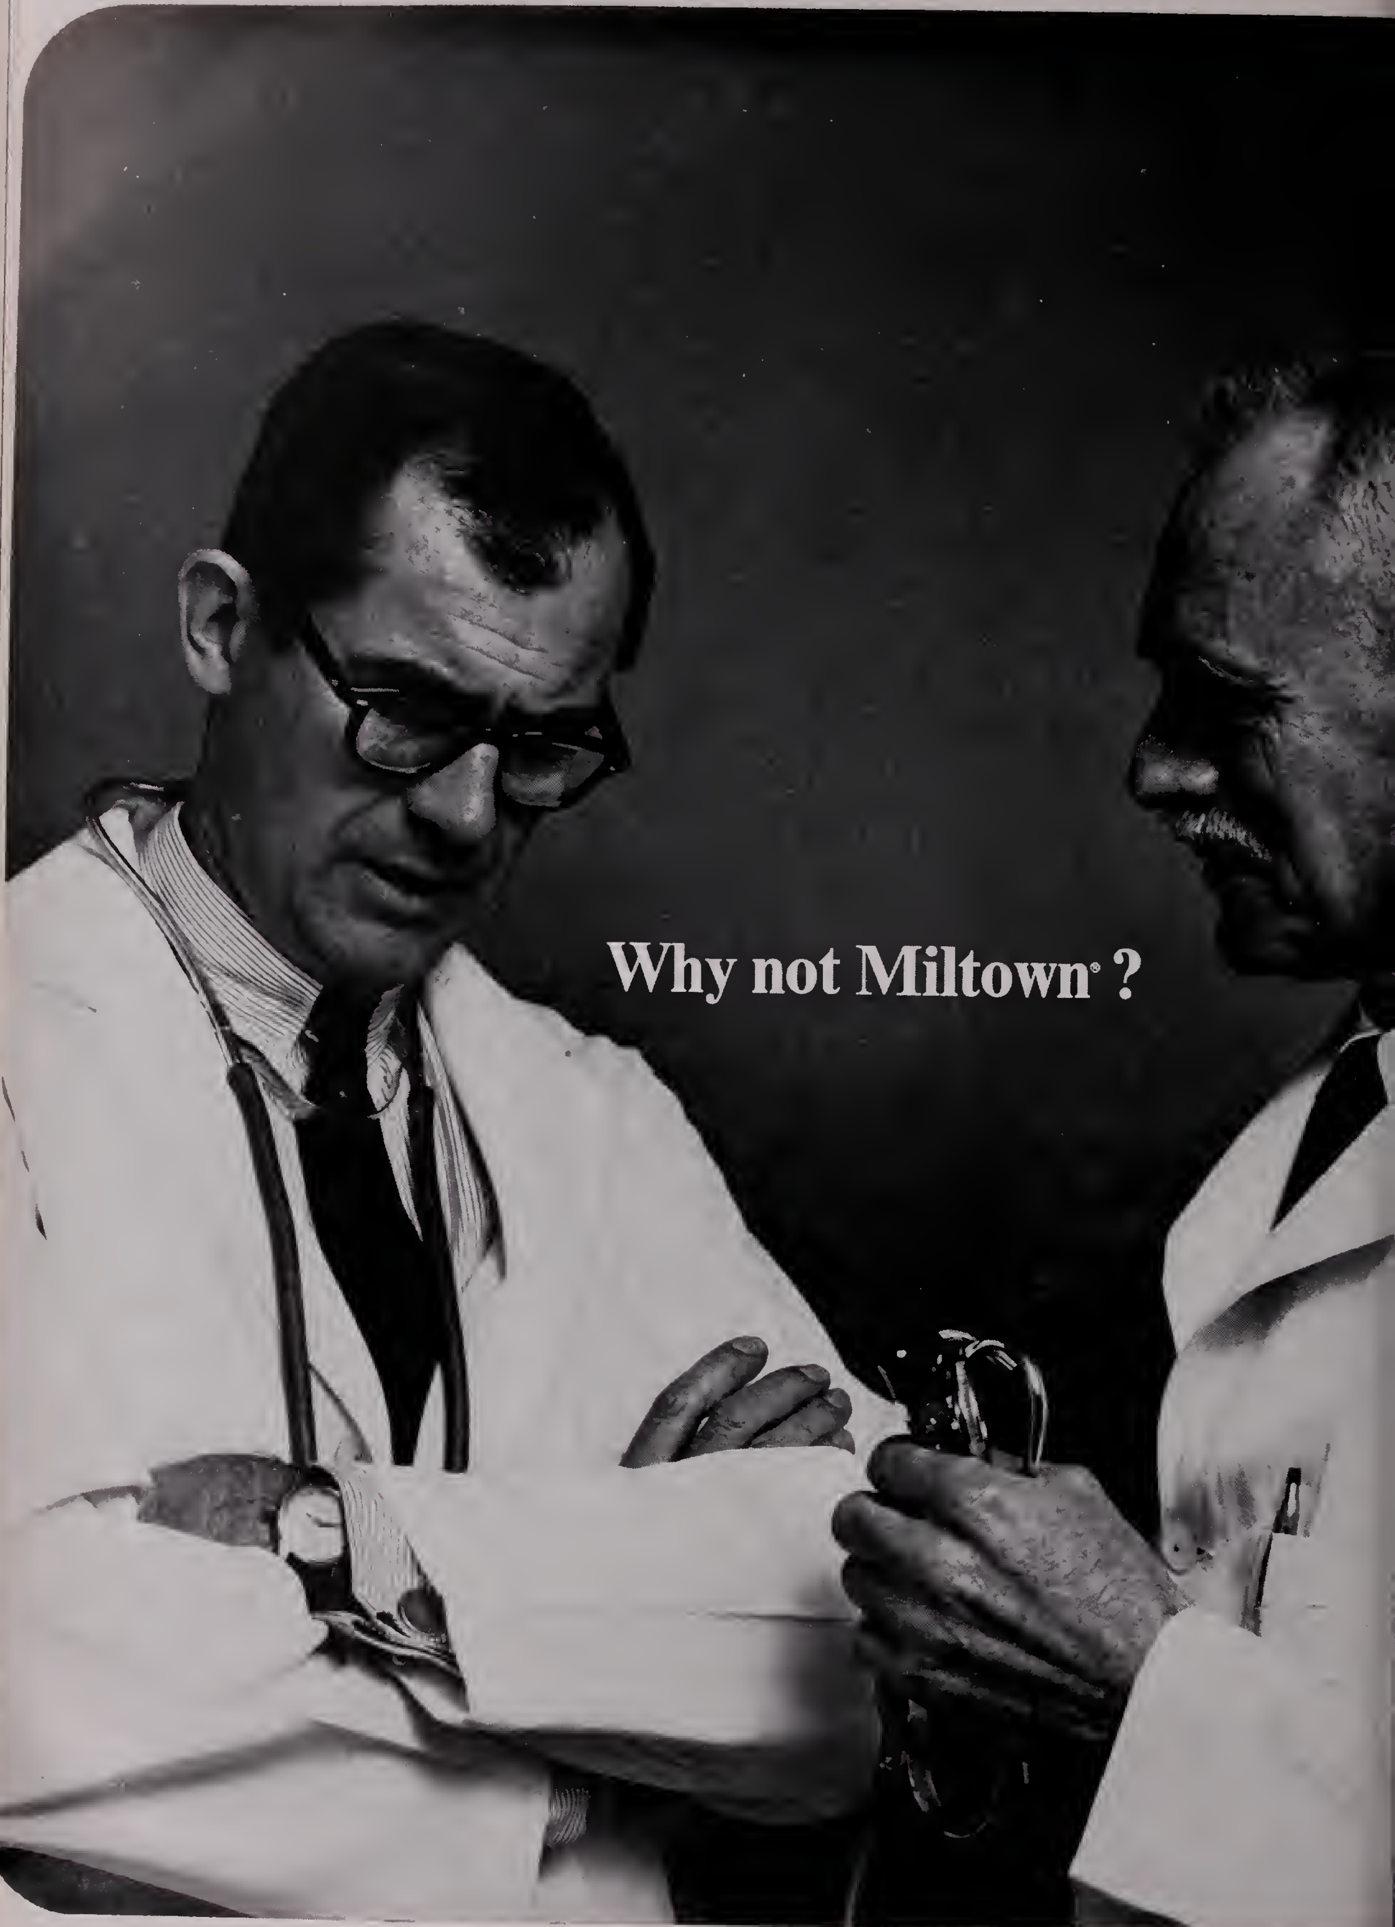
Dr. Arnold Larson of Detroit Lakes has retired from the practice of medicine after completing thirty years of practice in Detroit Lakes and forty-seven years as a Minnesota doctor. Dr. Larson stated in a recent interview that "It has been a most rewarding career."

* * *

NEW LOCATIONS: **Dr. L. A. Whitesell, Jr.** of Shakopee has opened up his own practice in Chanhassen . . . **Dr. Robert L. Hegrenes** and **Dr. Robert Cowger** of St. Paul will join the River's Edge Medical Clinic in Farmington in July . . . **Dr. Thomas C. Leach** of Minneapolis has joined the staff of the Babbitt Medical Clinic . . . **Doctors Edward C. Maeder** and **Clark A. Shattuck** of Minneapolis have opened up a new suburban office in Crystal . . . **Dr. Richard J. Snyder**, an army major stationed at Fort Benning, has been named to the staff of the Mankato Clinic effective June 1 . . . **Dr. Robert J. Knip** has begun a practice of his own in Ortonville.

* * *

Dr. Robert H. Ebert of Minneapolis has been chosen dean of the Harvard medical school. He will succeed Dr. George P. Berry, effective July 1. Dr. Berry is retiring.



Why not Miltown®?

There are few "nots" in Miltown® therapy

■ **Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.**

■ **The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.**

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its anti-anxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

Miltown®
(meprobamate)
